And the wheat fields are being cultivated, and the supply of potatoes and vegetables is beginning to come from them, although a considerable portion of the supply, as well as most of the fruit, still comes from San Francisco, and is consequently very dear. There is room in this vicinity for a few careful and experienced farmers, as the prices obtained are liberal, and the population is small but steadily increasing. Globe district probably numbers from 1,500 to 2,000 souls, and each soul has a body to be fed. The probability is, that the growth of population will be more rapid in the future than in the past, as the mines are deservedly attracting much attention, and I am told that

Globe City

Has doubled its population since the beginning of 1880.

They have a Methodist church, a new and neat edifice, presided over by Rev. Mr. Brooks; a private bank under the name of Stout, Fiske & Co.; a good, comfortable hotel for that region, and conducted by a San Francisco lady who knows how to make her guests comfortable; several lodging-houses and restaurants; half a dozen mercantile houses of character, and divers retail establishments; *several* saloons, whose number is somewhat disproportionate to the banks, churches, etc.; half a dozen lawyers, two physicians, county officers, etc. As all the traveling in that region is by wagon or on horse or mule-back, it is important to know that there are four livery establishments or corrals, and, finally, but perhaps as important as any other evidence of its growth, there are two weekly newspapers, viz.: the *Chronicle* and *Silver Belt*.

The "city" is situated on both sides of Pinal creek, which is for the most part a bed of sand, but which the summer rains converted into a respectable torrent, though sometimes a day or two sufficed to change it back again to its normal condition.

This creek divides the "city," and when it rains, it does so very effectually, as it was often impassable to pedestrians, as bridges have not yet invaded this virgin part of the Territory.

It may interest those who contemplate immigrating thither to know that there is a brewery on the creek, and an enterprising citizen amuses himself in winter by freezing ice up in the mountains, layer by layer, and night after night, until he has manufactured (for he uses tin pans for the purpose) cakes of about 100 lbs. each, which are stored in the ice house for summer use, and brought down as wanted.

Until the Indian outbreak, it was usual to see from 50 to 100

Indians About Globe.

They belonged to the San Carlos agency, and a party of scouts would come in and drive back all those who were without the proper passes. Now the town is quite free from this pest, for a more worthless lot of vagabonds I have never met with.

So long as the Indians are handled as they now are—located on reservations in the heart of the Territory, and allowed to roam about the country outside the reservation, procuring, as they do, arms, ammunition and fire water—there will be danger of constantly recurring difficulties, which, in so sparsely settled a country, will deter even many of the bold prospectors from pursuing their vocations, on which the growth of the population and the development of the mines so greatly depend.

Globe Mines.

The mines in Globe district are, as yet, few in number, but the prospects of discoveries are many. Enough has been done to point to Globe district as one of, if not *the* most promising in Arizona.

The famous Silver King mine is about 25 miles west of Globe City and near the border of Pinal and Gila counties. The MacMorris mine is about 15 miles north of Globe. The McMillan is about the same distance northeasterly, and silver mines of great promise lie all around it, but chiefly to the north and west.

Among the most conspicuous recent discoveries and developments are the Etna, Pioneer, Kentuck, Rescue and A. Lee, which make excellent showing. In the Mineral Creek district are the Mineral Creek Mining and Milling Co., El Capitan, Little Chief, Alta, Highbridge, Clara May, Aguirre, Quaker and Shakespeare. But there are many fine indications besides, where only the bare assessment work has been done, as the discoverers are generally miners or poor men who find it difficult to do work enough to hold their claims. But perhaps the most remarkable feature in both these districts is the

Recent Development of the Copper Leads.

It has been known for years past that there were copper leads in the district of great promise; but as the search was for gold and silver, little attention was paid to them until last year, when some Eastern capitalists sent an experi-

THOMAS BENNET, Gen'l Agt., 319 California St., S. F.

TONITE.

Miners! Attention!

With the approach of winter, the dangers which attend the handling and use of all Giant Powders (Nitro-Glycerine mixtures) are increased.

The lives annually sacrificed in thawing or using frozen cartridges, should be a warning to all to abandon Powders which freeze at 42° Fahrenheit. All Nitro-Glycerine Powders freeze at that temperature, and now for the first time Miners on this Coast have an opportunity to AVOID THESE DANGERS.

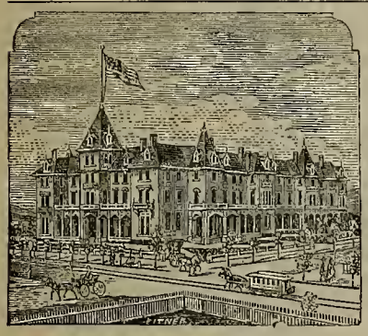
TONITE NEVER FREEZES!

NOR IS THERE ANY LIQUID SUBSTANCE IN IT TO LEAK OUT.

It is Always Ready for Use, as well in the Coldest Regions as the Tropics.

☞Miners are cautioned to take no stock in the slanderous reports about TONITE circulated anonymously or otherwise by the Giant Powder Company. They are all untrue.

TONITE POWDER COMPANY,
403 California street, S. F.



TUBBS HOTEL,

East Oakland,

Having been Thoroughly Refitted and Refurnished, Painted and Frescoed, is now Open for the Reception of Guests. Rooms can now be secured at the Hotel.

DEWEY & CO.'S

Scientific Press Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

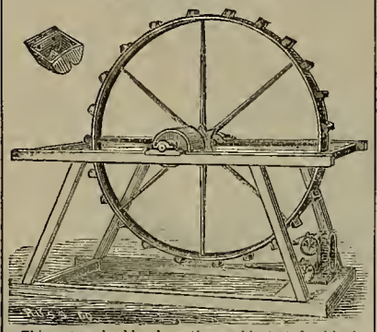
THE PELTON

WATER WHEEL.

(Patented, Oct. 26, 1880.)



This water wheel has been thoroughly tested with the Dynamometer, and utilizes 78% of the theoretical power; and underheads of water of 75 to 800 ft is guaranteed to give better satisfaction than any Turbine or other wheel ever offered to the public. The above per cent. is due to the peculiar shape of the buckets used. They do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized, without any part of the water coming in contact with the bucket following. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used. These buckets can be taken off in transportation, and can be replaced by new ones when worn out by sand in the water; also can be applied to wooden wheels when desired.

☞SEND FOR CIRCULAR.☜

Orders can be filled at short notice by addressing the undersigned,

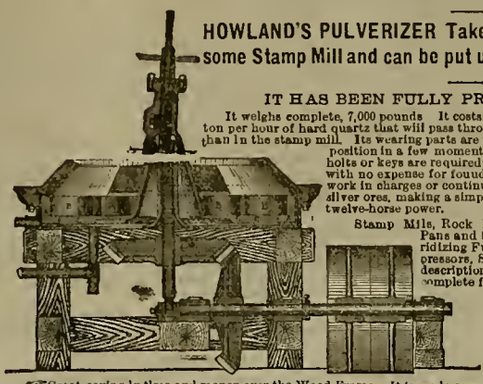
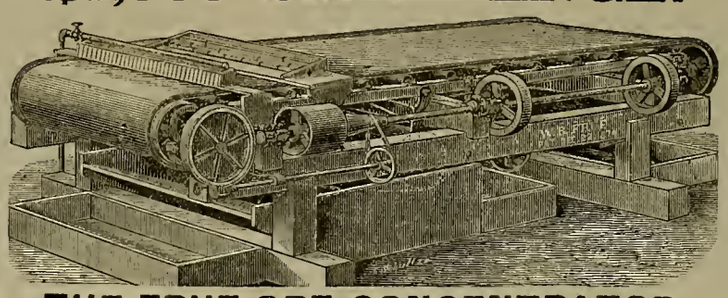
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.

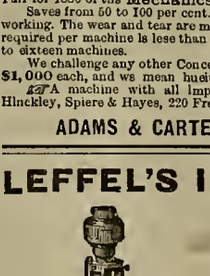
SHEET IRON PIPE.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery


HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

$1,000 CHALLENGE!


THE FRUE ORE CONCENTRATOR.
Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.
We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.
A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.
ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

LEFFEL'S IMPROVED WATER WHEEL.


PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING SEPTEMBER 20, 1881.

247,235.—GOVERNOR FOR ENGINE—L. W. Andrews, Live Oak, Cal.

247,149.—MACHINE FOR MORTISING DOORS FOR LOCES—T. N. Andrews, S. F.

247,237.—NUT LOCK—H. C. Behr, S. F.

247,296.—HARNESS—Geo. W. Blake, Port Townsend, W. T.

247,156.—TRICYCLE—H. C. Bridgeman, Milpitas, Cal.

247,172.—HAY AND GRAIN UNLOADER—A. C. Crow, Willows, Cal.

147,238.—QUICKSILVER FEEDER—P. C. DuBois, S. F.

247,328.—MONKEY WRENCH—Geo. T. Finegin, Plocho, Nevada.

247,193.—ORE FURNACE—O. Hofmann, Pinal, A. T.

247,255.—BED-LOUNGE—Wm. Kent, S. F.

247,203.—TRACTION WHEEL—A. H. Lighthall, S. F.

247,205.—CALF-FEEDING APPARATUS—M. O. Marsilliot, Port Townsend, W. T.

247,176.—EXCAVATOR—J. O. Dawes, Fresno, Cal.

247,387.—FRUIT DRIER—Mary A. McMastes, Antioch, Cal.

247,274.—GRAIN SEPARATOR—Jas Root, Black's Station, Cal.

247,276.—GRIP FOR CABLE RAILROAD—Stanford & Root, S. F.

247,429.—ELEVATING AND DEPRESSING PROPELLER—R. L. Stevens, Albany, Ogn.

247,433.—FIRE BACKS FOR MANTEL GRATES—Tresler & Loomis, Alameda, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

MDD RINGS FOR BOILER FDRNACES.—Patrick Dundon, S. F. Dated Sept. 27, 1881. No. 247,545. This invention relates to that class of boiler furnaces which have a douhlo wall surrounding the fire box, including an intermediate water space; and it consists in a novel method of securing the frame or mud ring whicb forms the floor or bottom of the water space, whereby it may be easily removed for the purpose of cleaning the water space or repairing whenever necessary in any case. The method of securing this frame at present is open to the objection that it prevents a thorough cleaning of the water space or making repairs, because of the difficulty of removiug the franio and the necessity of cleaning and repairiug by the old imperfect methods. The water space between the walls needs to he cleaned out whenever there is too great a deposit of sediment. This is done through hand-holee near the bottom of the water leg; hut it is ohvious that such a method is imperfect in its results. The manuer iu which the frame or mud ring is fastened in the water leg—namely, hy rivets passing through hoth plates which form the walls and horizoutally through the mud ring—makes a solid connection so that the mud ring cannot he taken out to allow the water space to he cleaned, or to allnllow repair, unless the rivcts are cut or drawn out forcibly. Tho object of this invention of Mr. Dundon'e is to overcome this difficulty by fastening the mud ring or frame between the walls of the water leg iu such a manner ae to render it easy of removal when necessary to gain access to the outer space.

GRINDING AND PULVERIZING APPARATUS.—W. C. Stiles, Nevada City. Dated Sept. 27, 1881. No. 247,585. This grinding apparatus consists of a large cylinder having its outer surface or periphery covered by a screen of the desired fiueness. Within this screen, and at a short distanoe from it, is another coarser screen. Midway between the side of the drum or cylinder is a heavy flange or ring, the inner diameter of which ie somewhat less than that of the inner screen, and it has a deep V-shaped groove in it. A smaller wheel is supported upon a shaft, so that its convex periphery, also V-shaped, will run in the groove before described. The ore or suhstance to hs ground is fed into the inside of the large drier, falling upon tbe coarse inner screen, from which it is oarried to the top by huckets, which discharge it hehind the small wheel, so that it is ground betwesn it aud the concave flange until it is fine enough to pass through the outer screen. That which is not sufficieutly fine is returned upon the inner screen hy inclined chutes leading from the outer to the inner one, aud will again he ground until it is fine onough to pass the outer screen.

HAY AND GRAIN UNLOADERS.—A. G. Crow, Willowe, Cal. Dated Sept. 20, 1880. No. 247,172. This invention relates to certain improvements upon a hay pitcher and stacker, patented Dec. 16, 1879, No. 322,303, and coneists in such peculiar construction as will enahle the implement to elevate the body of a loaded header-wagon, or a rack, or any such receptacle for hay and grain, and throw its load upon a stack or into a barn.

THE Colusa *Sun* wants a tax of $25 a year levied on every pistol.

Copper in Arizona.

(CONTINDED FROM PAGE 241.)

encsd man to "spy out the land." He selected ths best claims to bs found in tho district, and on a portion of thsm they organized a company already well known in ths East as the Old Dominion Copper Mining Co., and on ths others they organized the Borva Copper Miuing Co. Thsn there is the Takoma Co., the Globe, ths Carrio mine, and various others in embryo. I visited those mentionsd, which are the only ones, I helievs, which are being actively or systematically developed.

The Old Dominion

Takes the lead, the devslopments hsiug remarkahls both as to quantity and quality of the orc. It is unquestionably a permanent vein of solid red oxide and green carhonate, interspersed with glance, and averaging hy many assays 35% to 40% copper. It also carries free gold assaying as high as $200 per ton. It is worked hy thres tunnels on the vein and shaft, and winzs connecting principal tuunel with the lower level. This tunnsl has entersd ths hill over 300 ft., and for the last 50 ft. or morc, the vein is wider than the tunnel, growing widsr as they continue on and as they sink to the lower level. They will have two of Prescott, Scott & Co.'s 30-ton smslters on the ground next wsck, and expect to turn out 500 to 600 tons of bullion monthly from November 1st.

Besides this mins, they havs two claims, known as the New York and Chicago, soms seven milee distant, which thcy are working with equal energy, having a tunnel nearly 400 ft. long, shafts of 50 and 100 ft., and their ore is little, if any inferior to the Old Dominion. It differe in character, however, there being less red oxide and more green carhonate and agurite. The ledge is of unprecedented width, varying in the croppings from 10 to over 100 ft. wide.

When looking at these immense veins of ore, averaging over 30% copper in hoth cases, and remsmhering that the Lake Superior ores run from 1% to 6% copper, and that the Copper Queen in Cachise county (thie Territory) averages ahout 15% copper, one is impressed with the possihilities of euch mining property. The company, I learn, have made arrangements to order forward two additional emolters as soon as the first two are fairly running, and repeat this ae the mines are opened.

The Globe Copper Co. hase their hopee on their proximity to the mammoth lode of the Old Dominion company, their claim heing apparently one of the feeders to that lead. As yet, however, there is nothing heyond surface indications. They are sinking a shaft, run down 80 ft. or more, and hope, when they cross-cut, to find the vein. It is hut 60 days since they commenced operations.

Takoma Copper Co.

Have heen at work some six or eight months, and have uncovered near the surface some handsome glance and malachite. In sinking, they find red oxides and carbonates, hut await further developments as to the ahundance of paying ore hefore erecting smelters—a wise policy, and one worthy of imitation, for it takes a good mine to supply a 30-ton smelter day hy day.

The Old Dominion Co. estimate that they have about 1,500 tons from their development work to commence with, and can stope down from present workioge 100 tone a day for months to come. Meau while the mines are heing opened farther. Their capacity six months hence must he something enormous.

The Borva Copper Co.

Have 6,000 lineal ft. on a lead which shows hold outcrop for a great part of that dietance. They only commenced active operations six weeke ago aud already have over 100 tons of ore out from their workings. It is similar in character to the New York and Chicago.

The Carrie

Is a private enterprise. They have a smelter up, hut it has not yet commenced running. Their ore is chiefly green carhonate, and I will leave the emelter to tell the percentage, ae it depende on how well they separate the ore from the rock with which it ie interspersed.

Other copper enterprises are on foot in the vicinity, hut I havo described those most worthy of attention.

Considering how short a time has heen devotsd to opening these mines, the result of two or three of them is remarkahle, and the output of hullion next year may he a eource of surprise to our copper men.

ONE of the counsel retained hy the Government in prosecution of the Star-route cases, says: There has never heen any doubt about obtaining indictments in the Star-route cases. Grand Juries, although drawn pretty much in the same way as petit juries, rarely hold out against the Government, if it has any case at all, and the present Grand Jury is a very fair one, as far as the Grand Juries go.

A PERMIT for a hurial in consecrated ground was refused to a native Protestant at Xochiapa, Mexico, and the corpse lay decomposing for three days. Tbe civil authorities could offer no relief. When the Protestants organized a funeral procession a mob stoned it and threatened further violence, so a secret hurial took place.

ABODT 100 men are now employed by the Emigrant prospecting company, Silver City. The town already hegins to show signs of returning life.

News in Brief.

RIVERSIDE is experiencing a gsnuine boom in real estate matters.

THE loss hy the hush fires on Saugeen peninsula, Ontario, amounts to $500,000.

(FIRST EDITION ISSUED 1874).

Naturalists, Scientists, Teachers, Students, and Navigators will find the work not only exceedingly desirable, but in a degree indispensable. It is the only publication of the kind, and should be in all School, Public, Club, and Private Libraries.

DEWEY & CO.

Publishers of the MINING AND SCIENTIFIC PRESS, No. 202 Sansome St., San Francisco, Cal.

Agents Wanted.

IN the fall of 1883 overland trains of the Northern Pacific R. R. may hs expected in Portland. Much of the 800 miles yet to be completed is already under contract. Contracts for 1,000,000 ties for the Yellowstone division are just heing let, and those needed along Clarke's Fork have heen contracted for. Fifty-five thousand tons of steel rails have been contracted for for next year's delivery, in addition to 64,000 tons to he delivered this year.

THE O. R. & N. Co. are handling 800 tons of freight daily at The Dalles. There is a perfect ewarm of laborers working day and night at the wharf boats.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies, postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 202 Sansome St., San Francisco, Cal.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M P OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JAMES C. HOAG—California.
B. W. CROWELL—Yuba and Sutter counties.
D. W. KELLEHER—San Mateo and Santa Clara counties.
C. E. WETMORE—Alameda county.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F.D., at this office.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

ANNUAL STATISTICIAN of 1881.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 816 California st. Price, $4.

COPP'S "U. S. MINERAL LANDS, LAWS, FORMS, INSTRUCTIONS AND DECISIONS."—1881. 570 pp. In full law binding, $4.50; half law binding, $3, at this office.

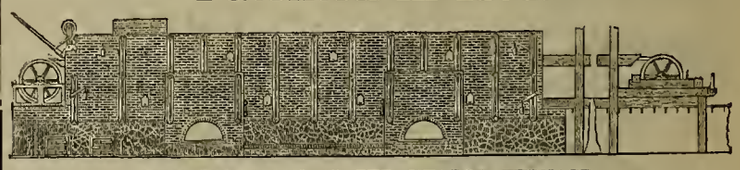
THE O'HARRA

CHLORIDIZING FURNACE.

Patented in 1878.



SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

—o—

An endless chain carrying convoyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenial sulphurate of silver up to from 84% to 95% of the assay.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, OCTOBER 15, 1881. VOLUME XLIII Number 16

The Hydraulic System of Draining Mines.

The hydraulic system of draining mines, as applied to the Chollar, Norcross and Savage mines on the Comstock, has attracted great attention among mining men, as so much depended on its proper working. Some portions of the castings were not sufficiently heavy when the system was first tried, and several breaks and delays occurred. These accidents caused many to believe that the system was a failure, but they were due to defects in minor details, not in the general plan. The pumps have now been some months at work successfully, and their workings have set at rest all doubts as to the success of the hydraulic system. The machinery was designed and built at the Risdon Iron Works in this city.

R. S. Moore, the son of Mr. Joseph Moore, superintendent of the Risdon Iron Works, graduated from the University of California a few months since, and at that time read a thesis on the hydraulic system of draining mines, describing not only the system, but making all the mathematical calculations necessary in its construction, and carefully considering the most essential points arising during the operation of the system. This thesis is a most scholarly production, far above the ordinary papers read on such occasions. The subject itself was an unusual one, and it was treated in a masterly manner. It may be stated here, by the way, that young Mr. Moore is now hard at work at his trade at the Works, and with his practical experience and scientific knowledge, will, no doubt, in time, achieve a reputation for skill in mechanics equal to that his father now enjoys. By permission of young Mr. Moore, we extract from his thesis that portion describing the system in general:

To all those who have watched the progress made within the past few years in developing and prospecting the deep quartz mines of the Pacific coast, this hydraulic system is at once familiar. But for the information of those who have paid little or no attention to this matter, I will state briefly the reasons for its adoption upon this coast.

In the earlier days of mining in this country, neither great depths nor great quantities of water had to be dealt with, and a simple water wheel, generally a hurdy-gurdy, driven by a small jet from some high head, was the prime mover. A pump-bob of the simplest construction and a bucket-lift, all of wood, completed the pit-work. Many a rig like this may be seen running yet, where placer diggings are being worked.

As the mines increased in depth and larger quantities of water had to be raised, larger engines and heavier gears were necessary to do the work, and as these depths became very great, the weight of the pit-work increased enormously, until finally the rate of speed, which is determined by the weight of the mass set in motion, had to be decreased beyond all practical working limits.

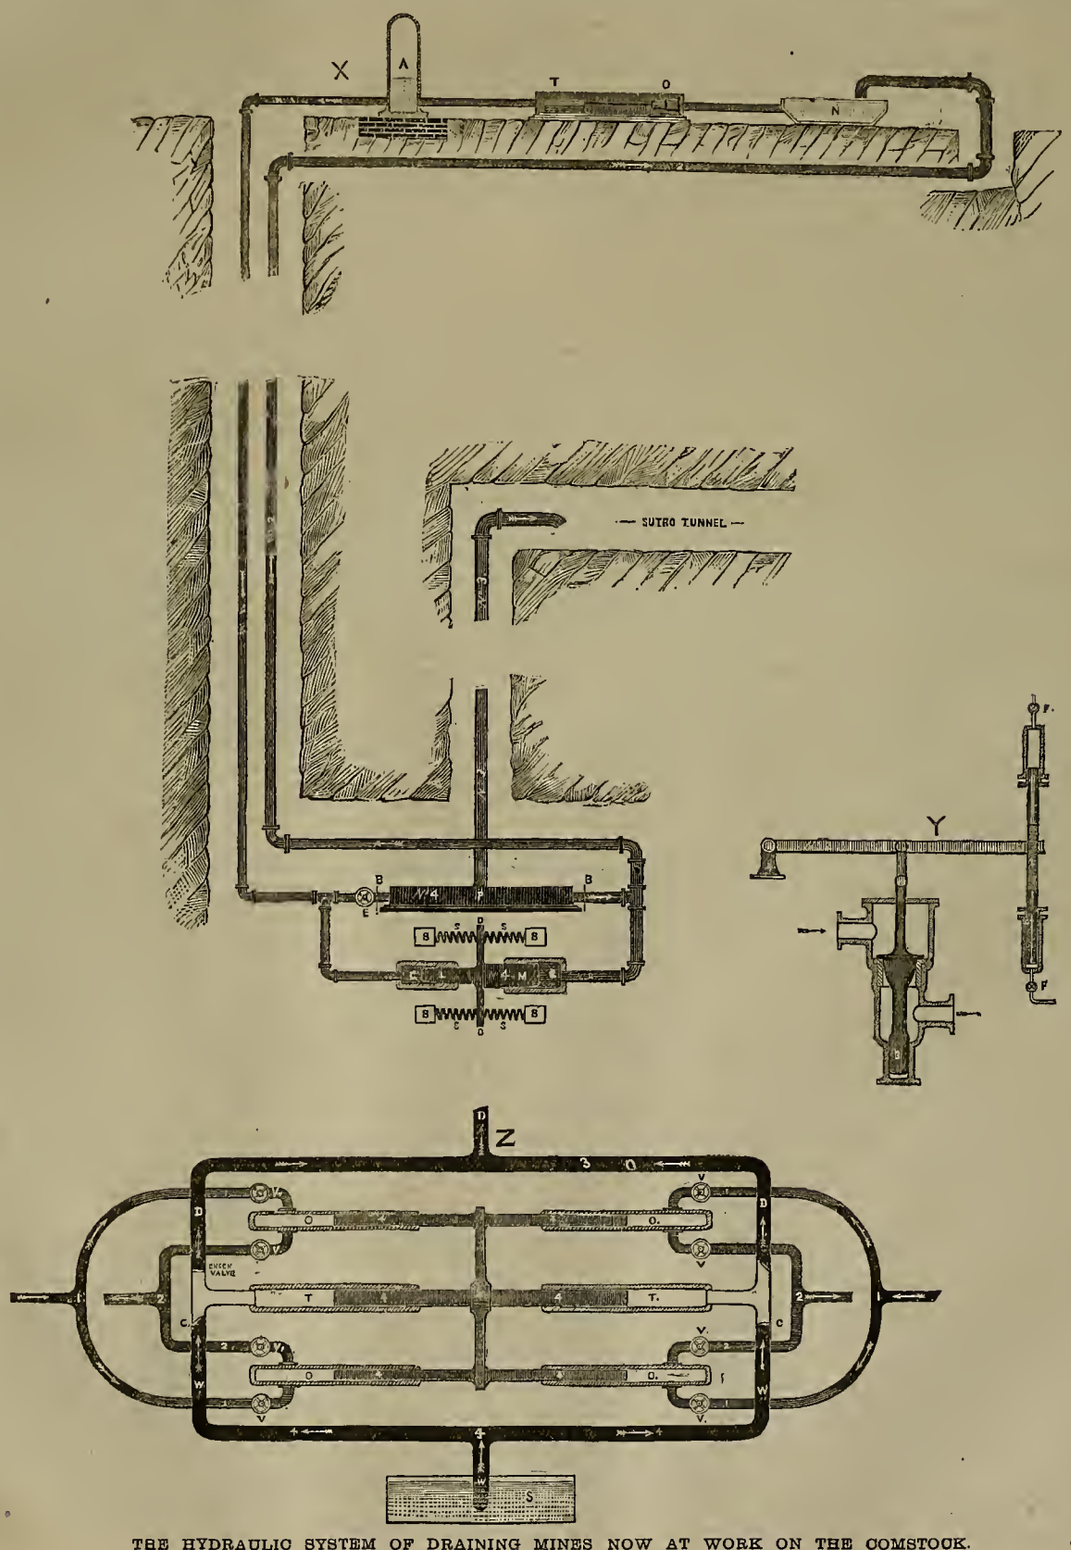
The question then presented itself: What system of pumping can be adopted that will meet all the difficulties that are ever present where heavy pumping works have to be constructed, and that will also meet the peculiar difficulties that have to be encountered in developing the great gold and silver bodies of ore that lie within the bosom of the Sierras?

The mining engineers of the coast differed in opinions. Plans of a hydraulic drainage system, which would do away with all kinds of pump-rods and pit-work, were now prepared, but owing to the fact that the system had never been tried, excepting in Europe, where mines of small depths had been drained, these plans were not accepted and the old style of pumping still adhered to.

Last year, however, the managers of the Combination shaft in Virginia City adopted this hydraulic system, and at the present writing bids fair to revolutionize the draining system of the Pacific coast.

By referring to the drawings of the general plan, it will be seen that the mine to which this system is applied, is 2,400 ft. deep, also that the water to be pumped is to be raised from the 2400 level to a hight of 800 ft. and discharged into the Sutro tunnel, through which it is run off. Upon the 2400 level is erected a pair of hydraulic pumping engines (marked *P* in the drawing) which receive their pressure water through supply pipes from the surface. By these two pumps (as will be fully explained hereafter) the drain water is raised through discharge column to Sutro tunnel, and the water used in doing the work of pumping is sent back through the return pipe to a reservoir, *N*, on the surface. Upon the surface there is a cast-iron accumulator, *A*, which is 60 ft. high and 25 inches in diameter. In this accumulator there are but 20 ft. of water, the remaining space being occupied by air

This air is kept constantly at a certain



THE HYDRAULIC SYSTEM OF DRAINING MINES NOW AT WORK ON THE COMSTOCK.

(CONTINUED ON PAGE 256.)

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Mines and Mining on the Klamath—Hydraulic Operations.

EDITORS PRESS:—What you say in your issne of September 24th about good opportunities for engsging in hydranlic mining along the Klamath river is correct. The few companies at work here, operating for the most part with imperfect appliances and in a small way, are all doing well, as they always have done. These companies along this part of the river are the Woods, Bailey, Mucamuc, Del Norte or Richardson, Furguson & Frazier, Reeves, China Creek and the Gordon & Lane, besides a number of smaller claims which, depending on the gulch water near by, are able to run for only a short time every year. At Wingate hill, eight miles below here, and at Bunker hill, eight miles still farther down, several prosperous bydraulic mines are being worked, some of them on what, for this section of country, may he considered a large scale. A number of mines at Indian creek and Classic Hill have also done well this season.

An Isolated Region and an Unprogressive People.

That hydraulic mining is not here conducted on a more extended plan is because of the non-progressive ideas of those engaged in the business, and who, notwithstanding the improvements introduced elsewhere, still carry it on in a restricted and primitive way. And this, not because we lack here the auriferous gravel, the outlet, water, or any of the other olements essential to large and profitable operations. On the contrary, these are all here present to a greater extent than usual—they may he said to exist to an eminent degree; that they have not heen more largely availed of heing due solely to the cause above mentioned.

Why this indnstry has remained so backward here is owing to a variety of causes, such as our remote and isolated position, deterring the introduction of more recent improvements and preventing the investment of capital in our mines. Time and cost of freights and travel considered, this section of country is as distant from San Francisco as Salt Lake City or Tucson, and nearly as far off as Denver, Colorado. Not until the past few years did any railroad come within 350 miles of this camp, the nearest point on any heing now 200 miles away. This has heen a great detriment to the mines, keeping out the agents of moneyed men as well as the promoters of new ideas, methods and devices.

Then, our population being comparatively sparse, the mines here have not heen depleted as rapidly as in the more accessible and densely populated districts of the State. Claim owners having been able to make good wages working on a limited scale, and with the cruder implements of earlier times, have not beeu forced nor bave they sougbt to expand operations or substitute for their mediocre apparatus, others of more modern and effective patterns.

To illustrate, while we have water in good supply, the ditches are mostly short and small, very few of them delivering their water under a pressnre of more than 100 ft., the pressnre in most cases being much less. Great quantities of water that could easily be brought upon the mines are suffered to run to waste, while thousands of acres of good gravel lie unused and even unclaimed. Some claims after having heen outfitted and supplied with water, are run only dnring the dsy, reducing production to the extent of a third or more. The most of the sluices are short and narrow, and I do not think a single undercurrent has ever yet been put in along the river, such is the inefficient and shiftless manner in which hydraulic mining has heretofore heen carried on in this part of the country.

That the hydraulic miners here are so much behind the times finds its explanation in part in the fact that ours has not heen a migratory population, Siskiyou and Del Norte having suffered hut little from the Frazier river, Washoe and similar excitements as compared with most of the other mining counties of California. The early residents of this section have mostly remained where they were, the majority of our miners having beeu here from 25 to 30 years. Not having left and returned, as has heen so much the custom elsewhere, they have not brought in and rendered available the many new inventions and improved modes elsewhere in use.

Something Gained by the Stay-at-Home Policy.

On the other hand, while our miners have so foregone the benefits of these more advanced methods, they have, by reason of the economy of money and time, effected through this etay-at-home policy, managed to possess themselves of extensivo and valnable mining properties, the most of them having meantime accumulated some ready cash and a few become quite rich. Out of this condition of things has grown not only an indifference to these moderu improvements and an unwillingness to engage in new enterprises, but also a general disposition to sell out their possessions here and betake themselves to other localities, where, after eo many years of isolation, they can enjoy more of the comforts and privileges incident to older communities. Hence the numerous good openinge here, as stated in your article, for tbe investment of money in hydraulic mining.

What you say of the favorable conditions that exist here for the prosecution of that business is true enough, and will he more than sustained by the actual facts. I do uot mean to say that the field here is a very broad one, but so far as it extends it is certainly most inviting; so much so that gaining publicity tbrough such articles as that in the PRESS, it may be expected to meet with wide appreciation and be early availed of.

River-bed Mining.

Of wbich there is a good deal being done along both the Klamath and Scott rivers, has been well prospered the present season, a great deal of gold having already been taken out, with the most and the best part of the season yet to come. This branch of mining is carried on by means of wing damming, these structures heing run out about half way across tbe river and then carried down the stream for 1,000 ft. or more. When finished they inclose a large body of water, which is pumped out hy means of huge wheels attached to long shafts projecting beyond the wing dams and revolved hy the current, these wheels also lifting the water that afterward seeps into the pit.

As little or nothing can he done towards building these dams till the water goes down in the summer, work once commenced has to he driven ahead with all possible expedition, since, with the rise of the river in the autumn, there is an end of operations for the season, the period of gravel extraction hardly ever extending over two and a half moutbs or three at the most. While it lasts every hour is improved, relays of men heing kept busy day and night. The gold hearing material is raised from the pits with derricks or carried out in wheelbarrows and emptied into the sluicee prepared for receiving and washing it, this stuff, where the pits are not too deep, heing thrown up into the sluices with shovels. As many large bowlders are apt to he encountered in excavating these river beds, powerful derricks are required for lifting and swinging them around out of the way, these bowlders heing sometimes piled up on the banks of the pits to a hight of 50 or 60 ft., and covering many acres.

Although the cost of opening and working one of these river-bed claims is great, they never fail to pay well if tbe season proves favorable—the quantity of gold dust taken out hy some of these companies boing large. In some cases the value of the gold extracted in a single season amounts to as much as $200,000, a large proportion of which usually cousists of net profits.

As it is the custom with this class of miners to continue operations till a rise in the river puts a stop to them, they are apt to loose their wing-dams, wheels, pumps, and even tbeir flumes and derricks every fall, the stream rising suddenly on them and carrying all away. And thus it happens tbat, with each recurring summer they have to rebuild tbe whole, a tbing they could not afford to do wore not their yearly earnings very large. OLD SETTLER,

Happy Camp, Del Norte Co., Sept. 27, 1881.

Tunnel Sites and Blind Lodes.

The Commissioner of the General Land Office has decided that the requirements of location and notices of a proposed tunnel apply only where blind lodes are sought to be discovered. And be has also decided that where a party runs a tunnel to develop a known lode, already discovered and located, notice of such intention is not required, and a tunnel location nesd not be made.

The decision in full is as follows:

GENTLEMEN: I have examined the protest submitted hy M. D. Cooper against the issnance of patent to Henry M. Hoyt *et al.* for the Mark Twain lode and mill site, lots 344 A and B, situatsd in Mt. Sneffel's mining district, Ouray County, Colorado, and embraced in mineral entry No. 190, of the series of your office.

The record of said entry shows that the Mark Twain lode was duly located, and that the possessory title is vested in the applioants for patent. The application for patent was filed in your office April 30, 1880, due notice of which was given in the manner prescribed by law, the period of publication expiring Septemher 4, 1880. February 3, 1881, the claimants entered and paid for the land.

Mr. Cooper alleges that during the year 1880, no work whatever was performed upon the Mark Twain lode, and that on the 22d of January, 1881, he made a re-location of the same under the name of the Ida City lode.

Protestant further allegee that "said H. M. Hoyt *et al.* attempted to develop eaid Mark Twain lode by rnuning a tunnel on the Wheel of Fortune lode (a claim owned by Hoyt *et al.*), a claim or lode distant from said Mark Twain lode about 1,200 ft., and lying at right angles with the said Wheel of Fortune lode, the eaid H. M. Hoyt *et al.* not heing owners of the lode or surface ground intervening * * * for the development of said mine or mines," etc.

By an act of Congrese approved February 11, 1875, it is provided that "where a pereon or company bas or may run a tunnel for the purposes of developing a lode or lodes owned hy said person or company, the money so expended in said tunnel shall he taken and considered *as expended on said lode or lodes*, whether located prior to or since the passage of eaid act (May 10, 1872); and sucb person or company shall not he required to perform work on the surface of said lode or lodes, in order to hold the same as reqnired by said act."

Protestant admits that a tunnel bas been commenced on the Wheel of Fortune lode snd run for the development of tbe Mark Twain lode, and that a sufficient amount has been expended upon or in said tunnel to maintain the possessory title to said lode during the year 1880; hut contends that such expenditures cannot be held to apply to said lode, because the line of said tunnel was not located and marked upon the surface of the ground by stakes; hecanse no notice was posted at the mouth or face of such tunnel, describing the purpose for which it was run; and because no copy of such notice was filed for record with the Mining Recorder, etc.

Inasmuch as there is notbing in the law or instructions of this office requiring these things to be done, I fail to perceive the force of the reasons assigned. When a tnnnel is run for the purpose of discovery of "hlind" lodes, under the provisions of Section 2323 R. S., it is proper, and the regulations require, that due notice of such tunnel shall be given, in order that other persons may not prospect for lodes along the line of such tunnel, which by law are vested in the tunnel claimants so long as they shall prosecute the tunnel with due diligence.

But thsse instructions are not applicable to tunnels run in accordance with the act of February 11, 1875, for the purpose of developing lodes already discovered and located. Indeed, said instructions were promulgated long prior to tho passage of said act, and there exists not the slightest reason why any notice whatever should have beeu given to the world as to the manner in which the claimants proposed to develop their claims, as the rights of third parties could not by any possibility he affected therehy.

Admitting all that is alleged hy protestaut, there appears to be uo reason why patsnt should not issue to the applicants.

The protest is herehy dismissed.

J. A. WILLIAMSON, Commissioner.

Electricity in Agriculture.

It is only fitting that agricnltnre should share in the present interest in electrical appliances and machinery, and that while the manufacturer is promised cheap power and the transportation companies cheap motors, the farmer should bave some encouragemsnt that perhaps some day he may plow and rsap and thresh with lightning rather than horseflesh or steam. Such indeed is the present promise, and it adds interest to the promise to know tbat be who makes it, Dr. Siemens the leading Englisb electrician, is in fact a country gentleman and is actually training his newly contrived devices to do horticultural and agricultural work.

The last official announcement of what Dr. Siemens has accomplished and bopes yet to attsin is fonnd in an address he delivered last month before the Royal British Association for the Advancement of Science, of which reports come in our last London oxchanges. His experiments and their results are too extended for us to reprodnce them in detail, but we shall endeavor to catch a few of the leading concln-sions and achievements whicb will show tbe direction of progress in this field.

First, we may remark that Dr. Siemens has experimented in two main lines at least. One is to test the effect of the electric light upon the growth of plants; the other is to make the motive power of electricity available for ordinary farm work. In the first attempt that of growiug plants qnite remarkable results have been attained; in tbe second there are some satisfactory results and some splendid promises. In growing plants hy the electric light, Dr. Siemens met with some failures at first, for he soon fonnd that there must he some rules observed in the manner of admitting the light, etc. His arrangements and appliances consisted of a high pressure steam engine of six-horse power nominal, which gives motion to two dynamo machines connected separately to two electric lamps, each capable of emitting a light of abont 4,000-candle power. One of these lamps was placed inside a glass house of 2,318 cubic ft. capacity, and the other was snspended in the open air at a hight of 12 to 14 ft. over some sunk greenhonses. The waste steam of the engine was condensed in a heater, whence the greenhouses take their circulating snpply of hot water, thus eaving the fuel that would otherwise he required to heat the stoves. The experiments were commenced on Octoher 23, 1880, and were continued till May 7, 1881. The general plan of operation consisted in lighting the electric lights at first at 6 o'clock, and during the short days at 5 o'clock, every evening except Sunday, continuing their action until dawn. The results of thie treatment with different seeds and plante were as follows: Peas which had heen sown at the end of Octoher produced a harvest of ripe fruit on February 16th, under the influence, with the exception of Sunday nights, of continnous light. Raspberry stalks put into the house on December 16th produced ripe fruit on March 1st, and strawberry plants put in about the same time produced ripe fruit of excellent flavor and color on February 14th. Vines which broke on Decemher 26th produced ripe grapes of stronger flavor than usual on March 10th. Wheat, harley and oats shot up with extraordinary rapidity under the influence of continnous light, but did not arrive at maturity; their growth having heen too rapid for their strength caused them to fall to the ground after having attained the hight of about 12 inches. Seeds of wheat, harley, and oats planted in the open air and grown under the influence of the extsrnal electric light produced, however, more satisfactory results; having heen sown in rows on January 6th, they germinated with difficulty on account of frost and snow on the ground, but developed rapidly when milder weather set in, and showed ripe grain hy the end of June, having been aided in their growth hy the elcctric light until the heginning of May. Douhts have been expressed hy some botanists whether plants grown and brought to maturity under the influence of continnous light would produce fruit capable of reproduction; and in order to test this question, the peas gathered on February 16th from the plants which had heen grown under almost continuous light action were replanted February 18th. They vegetated in a few days, showing every appearance of healthy growth.

The effect of the electric light uhon the size and quality of the fruit produced is striking. Dr. Siemens describes especially the heneficial influence of the electric light has been very manifest npon a banana plant, which at two periods of its existence—viz: during its early growth and at the time of the fruit development—was placed (in February and March of 1880 and 1881) under the night action of one of the electric lights, set behind glass at a distance not exceeding two yards from the plant. The result was a hunch of fruit weighing 75 lbs., each hanana heing of unusual size, and pronounced hy competent judges to he unsurpassed in flavor. Melons, also, remarkable for size and aromatic flavor, have been produced under the influence of continuous light in the early spring of 1880 and 1881, and Dr. Siemens is confident that still hetter results may be realized when the best conditions of temperature and of proximity to the electric light have been thoroughly investigated. His object hitherto has rather been to ascertain the general conditions necessary to promote growth hy the aid of electric light than the production of quantitative results; hut he is disposed to think that the time is not far distant when the electric light will be found a valuable adjunct to the means at the disposal of the horticulturist in making him really independent of climate and season, and furnishing him with a power of producing new varieties.

During the day-time Dr. Siemen's was obliged to keep up the fires under his boilers to secure steam, to maintain the temperature in the greenhouses. He saw that he could then use the energy to prodnce electrical power for work, when it was not needed for light. In order to utilize this power he devised means of working the dynamo machine also during the daytime, and of transmitting the electric energy thus produced by means of wires to different points of the farm where such operations as chaff-cutting, swede slicing, timher sawing and water pumping have to he performed. These objects are accomplished by means of small dyuamo machines, placed at the points where power is required for these varions purposes, and which are in metallic connection with the current-generating dynamo machine near the engine. The connecting wires employed consist each of a naked strand of copper wire, supported on wooden poles, or on trees, without the nse of insulators, while the return circuit is effected through the park railing or wire fencing of the place, which is connected with hoth transmitting and working machines hy means of short pieces of connecting wire.

All these details of work with the electric apparatus, Dr. Siemens says were under the charge of his head gardener, assisted hy the ordinary staff of under gardeners and field laborers, who probably never before heard of the power of electricity. Electric transmission of power may eventually be applied also to threshing, reaping and plowing. These objects are at the present time accomplished to a large extent hy means of portable steam engines, a class of engine which has attained a high degree of perfection, bnt the electric motor presents the great advantage of lightness, its weight per horse power heing only 2 cwt., while the weight of a portable engine with its hoiler filled with water may be taken at 15 cwt. per horse power. Moreover, the portable engine requires a continuous supply of water and fuel, and involves skilled labor in the field, while the electrical engine receives its food through the wire (or a light rail npon which it may he made to move about) from the central station, where power can he produced at a cheaper rate of expenditure for fuel and labor than in the field.

THE PARIS ELECTRICAL EXHIBITION has proven one of the most successful and at the same time the most remarkable special exhibit ever undertaken in any country. The *Scientific American* thus refers to it: "Upward of 1,800 exhibitore have contributed to thie pioneer display of the applications of electricity to scientific, industrial, and domestic affaire; and it is noticed as a significant indication of the rapidity of modern progress that the exhibition of a single scientific industry, and that a comparatively new one, should require more space than sufficed for an entire international exhibition of the arts and sciences a quarter of a century ago. The Palais de l'Industrie, with its 45,000 square meters of space, was ample for the World's fair of 1855. It is now crowded with electrical exhibits, and many pavilions of wood and iron have been erected around it for the additional epace required."

MECHANICAL PROGRESS.

The Degeneration of Steel.

What a superb career steel has renounced. It had shaped the world; it had carried out history and formed the nations; it had taxed the limits of languages, and the geography of character and thought; it had vanquished the strong; it had rebuked the proud; it had succored the weak; it had been the arbiter of honor and the accomplisher of justice. The sword was, as the ancient chronicler said, the oldest, the most universal, the most varied of arms, the only one which has lived through time. All peoples knew it; it was everywhere regarded as the support of courage, as the enemy of perfidy, as the mark of commandment, as the companion of authority, as the emblem of sovereignty, of power, of force, of conquest, of fidelity, and of punishment. And all this has steel abandoned—to become rails. Look at what it was, and what it is. Its aspect was brilliant; its habits were punctilious; its manners courtly; its connections were patrician; its functions were solemn; its contact was ennobling; even its very vices were glittering, for most of them were simply the defects of its superb qualities. It is true that it was sometimes cruel, and that its processes of action were distinctly sanguinary, but these reproaches apply to all other weapons, too. Throughout the ages it grandly held up its head and haughtily bore its name. It lost no caste when it allied itself with lance and dagger, with battle-ax and holm, for they were of its natural kindred; and even when, in later times, it stooped to generate such lowly offspring as razors, lancets, knives and needles, the world saw no real abasement in the act, for the chivalrous blade was still the image which represented steel to man. But now the whole character has changed; now, it has thrown aside its gallantry, its grace, its glory; now, it has forsworn its pride for profit, its pomp for popularity.

Steel is now bursting coarsely on the earth at the rate of thousands of tons a month. It is positively made into steam engines, and cannon, and ships, and all sorts of vulgar, heavy, uncomely, useful objects. Worse than all, it is becoming cheap! Steel cheap! The steel of old, the steel of legend and of story, the steel of the paladin and the chevalier, the steel of the noble and the brave, the steel of honor and of might, the steel that was above price, that knew not money, and cared naught for profit—that steel is no more. It has been driven contemptuously out of sight by metallurgical persons called Bessemer, Krupp and Siemens, and these destructive creators have put into its place a 19th century substance exactly fitted to a mercantile period, but possessing no tie whatever between time or fame.

No more steel will append its personal signature, its gloriously recognizable autograph, to the great events of history. The dagger that slew Cæsar, the glaive that Brennus hurled into the scale to weigh against the liberty of Rome, the ax that gashed off Mary Stuart's head, the knife that armed the hand of Charlotte Corday—of course they were not all steel, but they admirably represent the notion of it—are mere faded antiquities. Steel has other functions to discharge now; it has given up marking dates in the world's life, and has gone in for trade; it has ceased to be history, and has become actuality; it is in a state of new departure; it no longer incarnates a sentiment; it is nothing but a fact. It has turned its back on the blades of Damascus, on the armor of Milan, on the shields of Augsburg, on the rapiers of Ferrara, on the halberts of Flanders, on the poignards of Bilboa, and at this very moment is forsaking almost the last refuge which was left to it, and is deserting the marvelous sabers of Japan. In the place of its former glories it is taking up all sorts of low associations; it is being manufactured in big furnaces; it is being "cast," as if it were mere clowish pig iron; it is being rolled, as if it were uncouth "bar;" it is condescending to be boiler plates, and axle-trees, and driving shafts, and girders. To this is steel reduced.—*Blackwood.*

VARIATIONS OF BELT SPEEDS.—From experiments made, it has been ascertained that about two revolutions per hundred are lost in the transmission of motion by a belt. In ordinary practice this would be a slight loss, and would in no wise interfere with the usual manufacturing processes; but where there is a long train of gear repeated from shaft to shaft by belts, the loss becomes serious. It is clear that if the coefficient of loss by shippage be .98 for a single pair, which has been verified with great certainty by varying the tensions of the same belt, it will become equal to the successive powers—.98, .96, .94, .92, .90, and so on—so that after a succession of five speeds, the loss amounts to one-tenth of the calculated speed, and that at the end of 34 speeds the velocity will be reduced to half. From these considerations it appears that where it is required to transmit speeds as near determinate as may be, by means of hands and pulleys, it is necessary to increase the diameter of the driving pulley by its fiftieth part, or diminish the driven pulley in the same ratio.

TO MAGNETIZE A STEEL BAR.—A steel bar held in the direction of a magnetic needle, and struck several blows with a hammer will become magnetized.

Metallurgical Patents.

Among the patents granted at Washington on the 13th ult. was one to Paul Anbe, of Paris, France, for a new method of making steel. A patent for the same was granted him in France on February 14, 1881. Following is the inventor's claim: "The method of cementing iron, which consists in subjecting the iron to heat in a retort in company with substances, as described, which under heat develop hydro carbon gas and nitrogen with or without carbonaceous matter, as described, the subjecting the metal to an acid bath, and finally, at the described temperature, to dry hydro carbon gas, substantially as and for the purpose set forth."

At the same date a patent was granted to Jacob Reese, of Pittsburgh, for a "process of producing a metal high in phosphorus and carbon and low in silicon." Mr. Reese's claim is as follows: "1. The method of producing metal high in phosphorus and carbon and low in silicon, which consists in smelting iron ores in a blast furnace with suitable charges of limestone and phosphoretic basic slag to flux the metal and charge it with phosphorus to the desired degree, and then treating the metal high in carbon, silicon and phosphorus so produced in a silicious-lined open-hearthed furnace, to reduce the silicon, whereby a metal high in carbon and phosphorus and low in silicon is produced, substantially as and for the purpose hereinbefore set forth. 2. The method of producing metal high in phosphorus and carbon and low in silicon, which consists in smelting iron ores with suitable charges of coke, limestone and phosphoretic basic slag in a blast furnace and then running the molten metal into a silicious-lined open hearth and treating it therein until the metal begins to boil and the elimination of the carbon commences, whereby a metal high in phosphorus and carbon and practically free from silicon is produced, as and for the purpose hereinbefore set forth. 3. As a new article of manufacture, cast iron or pig metal high in carbon and phosphorus and containing not more than one-half of 1% of silicon, substantially as herein specified."

The Modern Uses of Steel.

At present there is but one sound reason why steel should not universally replace iron with advantage, and that is, that in some cases it is cheaper to employ iron. Statistics show us that the enormous quantities of steel now manufactured have hut little, if at all, affected the production of wrought-iron. It is, however, I am convinced, hut a question of time. When the day comes—and every day brings us nearer to it—when steel will be manufactured as cheaply as iron, then will wrought iron be a thing of the past among the great civilized nations.

One word as regards the employment of steel made by these modern methods of entlery. Cutlery manufacturers would tell you that it is useless for the purpose; nevertheless, on the Continent, it is very largely used, and in this country to a considerable extent. I do not hesitate to assert that, with suitable ores and proper care in the manufacture, steel well suited for cutlery can be made both in the open-hearth and the converter. An essential in the ore is that it should not contain phosphorus; with but a trace of phosphorus present, a good cutting edge could never be obtained.

If we glance back for a moment to review our history, we shall see that the open-hearth processes embody the same principle as the first process by which steel was produced, viz., the mutual action of carburized iron and oxide of iron on one another, and the Bessemer process is, after all, though a splendid offspring, only the natural descendant of the finery process, the origin of which, as we have seen, was due to modifications in the primitive blast-furnaces. There is perfect continuity throughout, and, after all, what more natural?—*Prof. A. K. Huntington, in Popular Science Monthly.*

Friction.

So eminent an authority as Prof. Sweet, says in reference to the question of economy by reduction of friction, that of two systems, one saving 10% by reduction of friction, and the other 20% in the use of steam, he would take that which led to a saving in friction, which of necessity implies saving in maintenance, attendance, repairs, delays, etc. This loss by attendance, repairs and delay is greater in small engines than in large ones. To get economy in friction there should be generous wearing surfaces, well fitted and properly lubricated, and the engine should be in absolute alignment. We often find shafts that are set in perfect line and remain so when at rest, but which are deflected by the strain put upon them while at work.—*Manufacturer and Builder.*

STEEL BOAT.—James Rees, of Pittsburgh, in speaking of the steel boats of the past and future, says the structure will now be made entirely of steel. Formerly, iron boats were built. Then iron frames with steel plates, steel having more strength than iron, with about half its weight. Now plates and frames are of steel, which further adds to the lightness, a desideratum where this style of light-draught boats are used. The one they are now building to run on the Chattahoochie river is of the latter description.

THE friction of a belt is double as much on wood as it is on cast iron.

SCIENTIFIC PROGRESS.

Galvanic Deposition of Iron.

Printing plates of stereotype metal, and especially those of copper (made by electrotyping), have a surface sufficiently hard and resistent to wear, to give many thousand impressions in the printing press before they show signs of wear—that is, where they do not suffer rough usage; and they are so cheap that there is hardly room for any material improvement upon them. Nevertheless, while we do not think much of our correspondent's suggestion to use iron-faced plates for printing, as a substitute for those before named, we readily accede to his request to know if any methods have been devised to deposit a galvanic coating of iron. Several such plans have been proposed, and we give the more important of these below. Boettger, in 1846, described a process for obtaining galvanic deposits of iron, and employed for this purpose a solution of two parts of sulphide of iron and three parts of sal-ammoniac. Klein improved upon this by using sulphate of ammonia for the chloride. As an anode he used an iron plate, but explains that he found it expedient to connect this with a copper plate. He found the deposits he obtained were very hard and brittle; but he succeeded in rendering them ductile by heating them to a red heat. Varrentrapp recommends that an iron wire be connected with the iron anode, and that the anode and cathode be brought within four or five inches of each other. He employs as his solution four parts (by weight) of green vitriol and three of sal-ammoniac, in 30 parts of water. When metal molds are used, he suggests that they be first silvered, and then given a yellow coating of sulphide by the action of sulphureted hydrogen, which allows the iron shell to come away freely. The current should be weak and constant to obtain the best effects.—*Manufacturer and Builder.*

ELECTRICITY APPLIED TO BALLOONS.—A late number of the *London Times* says: On Saturday last the Balloon Society inaugurated their session by meeting at Lillie Bridge, West Brompton. An address was given by the President, Mr. W. H. Le Fevre, C. E., on an electrical stationary balloon patented by M. Jules Goddard and M. de Fonvielle. A new application of electricity was about to be made, which, it was true, did not enable one to propel a balloon, but by which the system of aerial navigation would be considerably improved. The first step to be taken in making a balloon stationary was to prevent its gyrating. MM. Goddard and de Fonvielle had overcome this by means of a disk somewhat similar to the face of the compass placed in the center of the car poised on a vertical axis. When one side of the car was lower than the other, the disk or plate became instantly affected. An electric current was instantaneously transmitted to a magnetized point immediately opposite, which had a contrary effect, and placed the car in equilibrium. The Plante-Faure battery which produced the electric current would at the same time act on a small shaft running at the bottom of the car and turn a small screw. The balloon would thus neither ascend nor descend. This principle had been carried out successfully and practically recently on a small scale, and, he believed, would come into general use in a very short time. He considered that this was the most extraordinary discovery in connection with the storage of electricity that had ever been made. The result would be that the law of gravitation would be overcome, and that we should be able to suspend a body in the air at any altitude and in any position.

THE COMING GLORY OF SCIENCE.—Edward Atkinson indulges in a vision to this effect: If we can send thought and light over a wire; and if we can attach to the same post another wire by which to transmit electric power, so that every farmer may keep a small thunder-storm on tap in his barn to cut his fodder, milk his cows, and churn his butter, split his kindling-wood, and do all the heavy work and choring about the house; in short, if we are to accomplish here what is now being done in France, that is, operate an electrical machine by a small water-power on the farm, and run the plows, harrows, harvesters and threshers by electricity—if these things begin to be apparent, that are so bewildering that one even gets considerably mixed up in attempting to describe them, and is not quite sure what relation his parts of speech bear to each other—why, then, perhaps the millenium of the economist is nearer at hand than it has been supposed to be; "the time when intelligence and integrity and a very moderate amount of labor will insure so good a subsistence that it will not pay to be rich."

A NEW METAL.—M. Delafontaine, in 1878, communicated to the *Academie des Sciences* the discovery of a new metal in the mineral "samarskite," to which he gave the name "decipium." In the *Comptes Rendus* for July, M. Delafontaine states that he finds his "decipia" of 1878 to be a mixture of two new oxides, one of these being the radicle of the earth, found also by M. Locoq, and to which that chemist gave the name of "samarium," the other being his own "decipium." These names it is proposed to adopt in future.

The Density of the Earth.

Efforts have been made, at all times in which the spirit of investigation can be said to have existed, to ascertain the condition of the interior of the earth. There has been no lack of unfounded assumptions on the subject, and fanciful hypotheses were held even down to a period in which correct conclusions had been reached upon it—to the beginning of the 19th century. Alexander von Humboldt relates that he and Sir Humphrey Davy were several times invited by Capt. Symmes to join an expedition into the interior of the earth, which was represented as a hollow sphere having a large opening at the 82d parallel of north latitude. The idea of the existence of a hollow space within the earth was set at rest by the measurement of the average density of the planet, and the contrary view was advanced that the globe is a mass of great specific gravity. The constituency of this mass, whether it is fluid or solid, with only local bubble-like spaces, filled with fluid matter, has not been determined; but the calculations that have been made contradict the theory of a wholly fluid interior.

Several methods have been adopted for ascertaining the mean density of the earth, to the oldest of which a more accurate method has been added within a few years.—*Popular Science Monthly.*

A CURIOUS experiment has been made by Prof. Ira Remsen, of the John Hopkins University, Baltimore. It was instituted by him in order to see whether the lines of force in a magnetic field would have any influence on chemical action. For this purpose he placed a shallow pan of sheet iron, containing a solution of copper sulphate, over the poles of a powerful permanent magnet, capable of supporting 53 lbs. Outside the influence of the magnetic field pure copper was, of course, deposited uniformly on the iron; but when the saucer was set on the poles of the magnet, the deposit was reduced along the lines marking the poles, so that a groove or "ditch" was soon formed in the copper. When a still more powerful electro-magnet was employed, a still more striking effect was noticeable. The poles were marked by lines of no deposit, and in the space which they enclosed, that is to say, the space immediately over the poles, the copper was deposited uniformly, whereas beyond the blank outlines, the plating was heaped up in irregular ridges at right angles to the lines of force, and apparently coincident with the lines of equi-potential surfaces. By increasing the power of the electro-magnet, the action was intensified and the affected area widened. Prof. Remsen obtained circular ridges nearly four inches in diameter.

WHY SCIENCE IS OPPOSED.—Opposition to science is not the exclusive reproach of any one school of thought; it has been manifested by all. Theology withstood science, because it was itself identified with the old erroneous explanations of nature. Philosophy made a stand against science, because science circumscribed its field and subverted its ideals. Literature strove against science, because of its devotion to fact and its supposed unfriendliness to imagination. Art resisted science as unfavorable to the inventive and creative spirit. Science studied matter to understand its mysterious processes and discern its laws; the schools of culture all contemned the occupation of mind, and shrank from it as a descent into groveling materialism. Philosophy was most potent in its opposition, because it gave law to education and gave reasons to theology, literature and art.—*Prof. E. L. Youmens.*

ALUMINUM FOR TELEGRAPH WIRES.—German telegraphic engineers, it is said, have lately been making some promising experiments with aluminum as a material for telegraph wires. This metal can easily be drawn out to a much finer gauge than is possible with iron, and its conductibility is twice as great; but its greater cost has prevented its use for this purpose. It is now found, however, that an alloy of aluminum and iron can be readily made which will produce a wire much superior to iron as a conducting medium, while it is both finer and stronger, and also less susceptible to atmospheric changes.

COMPARATIVE VALUE OF STEAM ENGINES.—Hallauer's recent experiments have led him to the conclusion that the difference between engines of one and two cylinders, in point of economy, is very slight. In ranging from 80 to 8,000 horse power, with revolutions varying from 25 to 90 per minute, the expenditure of steam for a given amount of work remains the same for the same type of motor. The consumption for two cylinder motors are identical for Woolf and compound, whatever may be the volumes of the cylinders, provided the motors are regulated so as to give the maximum efficiency. The expenditures of steam in motors of one, two and three cylinders, suitably regulated and constructed, are so nearly alike that the choice may be governed in each instance merely by the fitness of the type of the engine for the particular purpose desired.

TO FIT A KEY.—Smoke the blank over a candle. Insert it into the keyhole and press it hard against the wards of the lock. The indentations in the smoked portions will show where to file.

Table of Highest and Lowest Sales in S. F. Stock Exchange.

Name of Company.	Week Ending Sept. 22		Week Ending Sept. 29		Week Ending Oct. 6.		Week Ending Oct. 15.

Mining Share Market.

Happily we are not this week without a sensation in the mining share market. This grows ont of a remark said to have been made by Col. Fair, to the effect that he entertains a hope, or at least a partial hope, that there exists and most likely always will exist a strong probability that ore, water, porphyry or somethiug else, will yet be strnck in the lower levels of the Comstock; and if not in the lower levels of the Comstock then in some other locality equally deep, dark and hot, but not so *damp* as the great sub-aqueous Washoe ore channel, with the exact sight of which locality he, the Colonel, is not at this time so well posted as he hereafter expects to be.

The annouucement of such a positive and unqualified opinion hy a man so cautious aou gnarded of speech as Col. Fair, prodnced uot only a profound sensation among mining men in this city, hnt created such a cheerful feeling over on the Comstock, that maoy of the old residenters were seen to *smile*, a few having gone so far in their glee as to get drnnk ontright. The nltimate effects of this new revelation remains to be seen.

Meantime, stocks wobblo after the fasbion most in vogue since the Sierra Nevada sqnash-out, a condition they are likely to maintain, at least for the present, and probably for a long time to come.

Tamalpais Hotel.—This most delightful and healthy resort has this summer been refurnished and painted throughont. The proprietor, Mr. W. G. Graham, formerly of Congress springs and other leading conntry hotels, is well known throughont the Pacific coast for his courtesy and attention to his guests. As a caterer he is nnrivaled. The beanty of the country aronnd San Rafael, and the mild and salubrious climate render it a most desirable residence dnring the fall and winter months.

Messrs. Parke & Lacy, tbe well-known dealers in mining machinery in this city, bave gradually enlarged and increased tbeir business, until now they inclnde other branches outside of machinery for use in mines. They bave a very full line of pumps for all sorts of purposes, to be run either by hand or steam. Have woodworking machinery, machinists' tools, steam engines, mill and mine supplies, steel and iron, flat and round wire rope, barbed wire for fences, etc. They will in tbe futnre make a specialty of wood-working machinery. Their stock of wire rope is very large and varied.

Cablegram advice is to hand, giving price of quicksilver in London at £7. Here the stock is very small, and price has advanced to 42 cents a pound.

End of a Noted Prospector and Explorer.

The Spokane Falls *Chronicle* of recent date contains a notice of the death of Joel S. Mead, who was killed by an explosion of powder at Joseph's prairie, in the Kootenay conntry, British Columbia. The *Chronicle*, in alluding to tho sad casualty, remarks that the deceased enjoyed the respect and esteem of all who knew him. This was undouhtedly the case, for Joel S. Mead was a man notable for his generosity, courage and other manly characteristics.

He arrived at San Francisco from New York, his native State, early in the summer of 1849, being then a mere boy, and had remained on this coast ever since. He was as fine a type of tbe California prospector and explorer as the conntry has ever produced, having a fondness for hardy adventure and new scenes that kept him constantly on the mining border. Possessed of a powerful frame and good general habits, neither deprivation, exposure nor toil deterred bim from undertaking the most difficult and dangerous frontier journeyings, he having been among the mining pioneers not only of California, bnt also of British Columbia, Idabo and Montana.

He was among those who visited Arizona and northern Mexico, traversing large sections of both, at a time when the bostility of tbe Apaches made it exceedingly perilous for small prospecting companies to enter that conntry. Mead and his party were on one occasion attacked by these Indians and several of bis companions killed, among them a yonng man to whom he was greatly attached. In pursuing the murderers the next day Mead advancing ahead of his party came suddenly np with the retreating savages, on whom be fired, killing two of them. Having exhausted his shots, he rushed ahead, and, grappling with a third, a powerful fellow, dispatched him with his knife.

Though a man of such cool and determined courage, the subject of these remarks was noted for his kind and peaceful disposition aod qniet demeanor. We have all too few men possessing the kindly virtues and noble attributes of Joel S. Mead.

The Paper Makers of the Eastern States have driven their works so steadily during the past year, that they have largely overstocked the market with every description of paper. So large bas this surplus become, that mntual arrangements are reported to have been recently made among the principal holders to make up a large amount for export to Europe, in order to relieve the home market of its burden. This fact may also be taken as very good evidence of the profitable natnre of the business and the little need that exists for the present rate of duties upon imported paper, which is in fact an indirect tax npon the consumers.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

At the Volunteer Mine.—*Ledger*, Oct. 8: Work has been suspended, the pipe for conveying water to the mine not being strong enough to sustain the pressure, and will bave to be replaced by stronger.

Jackman.—A lot of ore from this mine yielded but $5 per ton exclusive of sulphurets. But as the latter are rich, even this low grade ore can, it is thought, be worked with profit.

The Kennedy mill is still running, and the rock that is being crushed, pay.

Other Mines.—The new patent whim for the Median mine arrived safely, and has been running for several days. They have a ledge six ft wide, of ftne looking ore. The Talisman mill is being put in working order, and is expected to commence crushing to-day. At the Bunker Hill mill 20 stamps have been hung up temporarily, and the working force reduced. At the Amador Consolidated, with the exception of sioking the sump, everything is ready for tunnoling. The depth of 1,000 ft is accomplished, and as soon as the station is completed, drifting will be prosecuted vigorously. The laying of pipe for the Amador canal extension to Plymouth is in full blast. If no further drawbacks occur, the job will be completed by the time winter sets in. The Iowa, a 5-stamp mill, started up on Tuesday last, and in course of time will probably develop a paying mine. The Golden Eagle mine has closed down for this season. The owners sunk a shaft this summer 100 ft deep and found enough to warrant them putting machinery on next spring. The Amador Reduction Works is running on sulphurets from the Keystone mine and Stewart's chlorino works on sulphurets from the Mahoney.

CALAVERAS.

Ditch and Quartz Mill.—*Mountain Echo*, Oct. 4: The Lewis Co ,l near Robinson's ferry, is digging a ditch 10 ft wide and 8 ft deep, for furnishing water for the new quartz mill which they propose building in a short time, and which is to have 80 stamps.

Iron Mine.—James Sperry of the Big Trees has recently discovered and located an iron mine, about 1 mile north of Murphy's, in Calaveras county, which bids fair to rival the famous Iron Mountains of Missouri. The mill upon which the mine is located has been thoroughly prospected for nearly a mile and three-quarters, showing the same character of ore for the entire distance. It is not confined to a vein or lode, but is simply a mountain of ore of a very excellent quality known as brown hematite. Several assays have been made from the mine, some of which assayed as high as 60%.

Small Nugget.—A fine gold nugget worth $15 was picked up on Angels creek a few days since by a Mexican.

INYO.

Offer to Buy.—*Independent*, Oct. 1: Wm Hamilton —probably in the interest of Osbiston & Smith—has offered the Mexican owners of the Keynot mine, Beveridge district, $45,000 for it, which has been refnsed. A McKellips on the 30th ult., brought into Independence 7 ounces of gold, the proceeds of a 7 day's run of a little arastra near the old Chrysopolis mill. The gold is very fine, being worth $19 per ounce. Supt. Holt is overhauling the Rex Montis mill.

New Mill.—*Independent*, A new mill is about to be put up on the mines in Craig's canyon, Beveridge district. The ore is just as rich in free gold as any, while so far as opened the mines look equally as well. This matter of home enterprise and co-operation hits the nail square on the head, and the local community that supports legitimate operations of the kind is bound to win in the race for wealth and population, as against a place where business men lack enterprise or refuse help or credit.

Ore Ahead.—On account of a breakage down in the Taylor & McEvoy mill, the Keyoot mine managers have been compelled to discharge a lot of miners for lack of dump room. Some 250 tons of ore lie on the dumps at the mine and mill, of an even grade of from $100 to $118 per ton.

Where the Money Went.—A few instances can be called to mind which go to show where a good deal of wild "outside capital" was absorbed in this country in early days, when freights were enormous, Indians obstreperous and quartz mining in its infancy. On the other side of the river thousands of dollars lie in the sand, run off in tailings and amalgam. An illustration lately occurred at the old Chrysopolis mill, where the slum tanks are covered with 4 ft of accumulated debris. Out of the black earth near the mill a hoxful was taken in which to raise flowers. Seed were duly planted, but they failed to come up. Dumping out the earth, nearly an ounce of gold amalgam was discovered scattered through it. In the sand-covered tailings also of the San Carlos, Ida and Union mills there are small mines of amalgam and naturally oxidized sulphurets. Doubtless the old Union, Eclipse and present Brown Monster mills have equally valuable deposits, waiting a clean-up of former loss and waste. One would now-a-days like to have a small percentage of the precious metals lost at the old Olancha mill at the foot of the lake, and the Josephine, at Old Coso. The loss, through incomplete amalgamation at the Pioneer, Kearsarge and Greaser (afterwards the Silver Sprout, now the Rex Montis) mill in Kearsarge district, lies irrecoverable in the floods of the creek, as does most of the rich tailings from the old arastras at Fish Springs. The enormous slag piles at Cerro Gordo contain $9 per ton silver, as ascertained by recent assays. But the most notable instance is that of the Owens Lake Silver-Lead Co.'s furnace at Swansea, which operated from 1870 until 1874. There is left there a slag pile of 8,000 tons. After breaking it up and separating the particles of clear lead, the black slag assays $16 per ton.

MARIPOSA.

Hite Mine.—*Gazette*, Oct. 8. Is raising richer ore than ever from the new shaft sunk from the lower level. The body of ore is large and steadily increasing in width and richness. Whenever the river level is reached in this mine, look out for a bonanza of no ordinary magoitude.

South Hite.—The ore now being taken out here is of fair quality, and the prospect of reaching a permanent body of good ore soon is favorable. Modesto silver mine shaft which is down about 230 ft, shows a well defined vein about 2 ft wide, of ore said to be worth from $100 to $500 a ton. Other claims are being prospected in the same neighborhood.

The Diltz.—The shaft on the north side of the mine is downabout 75 ft, and a level is being run northerly on the vein from the bottom, which has reached 30 ft. The ore prospects well, and a fine lot for milling is being brought to the surface. The mines of the Cook Bros., near Coultonville are being worked successfully. The tunnel connecting the Potosi with the Mary Harrison, is about completed, and rich ore is being taken out. The prospects are that quartz crushing will soon be commenced here again. The Savage mine is developing rich ore. Some 3 or 4 weeks ago a pocket of about $500 was taken out, since which time the miners have about $3,000 in sight. Martin & Walling, and Bower Cave mines are being prosecuted with favorable results.

Banderita.—The 1,500-foot tunnel is about one-half finished, and when completed and connected by shaft with the upper works and levels, will probably develop a larger and richer body of ore than ever before.

No 9 mine with a steam mill and 30 stamps, is running with great success under its new management. The Washington mine with new compressor and drill, is making headway through an 8-foot vein of excellent milling ore, taken out below the 1,400 level.

NEVADA.

WILSON RANCH MINE.—Nevada *Transcript*, Oct. 8: We are informed by Prof. Frost, that in all probability the erection of the extensive mining works to be put up on the Wilson ranch property will be begun soon. The buildings and machinery will be of the most substantial character, and the property will be developed as rapidly as possible. The enterprise is being carried on very quietly, and in striking contrast with some of the much-puffed ones of adjacent districts.

THE CHAMPION BONANZA.—A shot in the Champion mine Wednesday night brought the whole breast of the drift into a body of rich ore, the extent of which cannot be estimated. This development indicates very strongly that the ledge which was discovered Friday night is not a blind one, but the main deposit for which the company have been striving.

FINDING THE BIG TUNNEL.—Next Monday the South Yuba Co. will begin retimbering the Big Tunnel, 18 miles above this city. The work will take some time, and in the meantime the water will be shut off from that ditch.

NEW HOISTING WORKS.—*Transcript*, Oct. 11: The carpenters have commenced the erection of the new hoisting works for the Meade M. Co on the Pennsylvania mine, and will push the work with all possible dispatch.

NEVADA CITY MINE.—Last month the new 10-inch pump of the Nevada City was lost and the mine flooded. Since then pumping and baling has been going on day and night, and yesterday the water had been lowered to the 350 level, and the disabled pump repaired. The remaining 80 ft of the incline will soon be dried. The mill will start again to-morrow.

THE BLUE TENT MINE.—The bedrock tunnel is completed and the upraise was commenced yesterday. It will take about 10 days to finish this work, and then the flumes will be put in readiness to start washing when the rains come.

A BIG pump weighing 2 tons exclusive of the fixtures, has been received for the Derbee mine. The present ones are not powerful enough to control the water.

PLACER.

CUROME.—*Herald*, Oct. 8: Some 4 or 5 years ago chrome iron was discovered near the Sugar Pine mills, on the Iowa Hill divide. The first attempt to commercially utilize it, according to the SCIENTIFIC PRESS, has been made this year, 100 tons having been shipped to San Francisco. The ore, which is of excellent quality, is found in irregular, disconnected masses imbedded in the country rock, and varying in weight from a few pounds to several hundred tons. On the largest mass yet found a shaft 20 ft deep has been sunk and does not pass through the deposit. It is expected that the prospecting now going on will develop a large and continuous ore body.

PLUMAS.

GREEN MOUNTAIN.—*National*, Oct. 8: While this company have milled a large quantity of ore, they have developed fully as large a quantity, and probably of better quality, in the Sulphuret ledge. There is lots of good pay yet in the White ledge—the one now being worked—as the mill returns show. The Green Mountain is a first-class "stand-by," a stayer in every sense of the word.

RICH GRAVEL.—The drifts lately run on the Newtown Flat claims have developed some very rich pay, and proved that the lead or pay-streak is some 40 ft in width. With 3 or 4 men at work last week, the clean-up amounted to $300, and the week before to about $100, some of the pieces weighing between $20 and $30. The gold is heavy, washed, rusty and black. The work at present is at a decided disadvantage, and when the claim is placed in proper shape, as it soon will be, there is no doubt but that some wonderful results will be shown.

THE CORBIN & MANSON.—The new shaft struck bedrock on Monday last, and the prospects are very favorable The depth is 80 ft. No washing has been done up to this writing, but small pieces of gold were picked up by the workmen, and the gravel and bedrock look first-class. The upper ground is also paying well, and everything looks right. Developments in the new shaft will soon be made, and we think some splendid pay will show up.

CHEROKEE.—Greenville *Bulletin*, Oct. 5: At the bottom of the new shaft of the Cherokee mine, and the depth of 240 ft, indications of quartz were found several days ago. A new level, No. 3, was started and a fine vein of ore found; the lode is from 5 to 6 ft thick, and of excellent quality. Enough is being taken out now to keep the mill running steadily, and the ledge continues to open out well. This mine has now been developed enough to prove that it is of great value. Within a distance of 240 ft, four separate ledges have been found, known respectively as the White, Josephine, Kettle and Old Bach ledges. The first is irregular in thickness, varying from 6 to 12 ft; the second is about 2½ ft thick; the third, 5 ft, and the fourth about the same. Enough of these have now been opened to furnish work for the mill for a long time to come.

THE Rock Island Hill mine, owned by Mr. W. Smith Dean, has developed well of late; the gravel, in the deepest part, is about 18 ft, and gold is found all the way from top to bottom. It is not intended to drift more than about 6 ft of it, however; this is all quartz gravel, free from bowlders. It gives 5 cents to the pan on every trial; one man can get out 10 carloads a day, and the gravel will give $5 to the car.

SIERRA.

BALD MOUNTAIN EXTENSION.—*Messenger*, Oct. 8: The clean-up here for one and a half days this week, was 27 ounces of heavy lead gold; in it a curiously shaped nugget of 8 ounces. But 4 men are able to work underground, owing to the impure air, that will soon be remedied on arrival of new iron air pipe, when a large force of miners will be afforded constant and lucrative employment. Last week 27½ ounces were sluiced from the upper or prospecting dump.

NOTES.—The Chinamen at work in the river beds hereabouts, still hold their position despite the recent high water, and are busy at work. J. W. Brown is busy making large sized iron water pipe for the Good Hope quartz mine. The Bonanza gravel claim, Howland Flat, continues on a dividend basis.

SHASTA.

SMELTING ORES.—*Courier*, Oct. 8: Assays of quartz taken from the Knox mine on Spring creek, are pronounced sufficiently satisfactory to justify the erection of smelting works. There are a number of rich ledges on Spring creek that would pay well if worked by improved machinery. The quartz is plentiful and rich in gold and silver, but base metals interfere with the amalgamating process

SISKIYOU.

Yreka *Journal*, Oct. 8: The Lime gulch claim on the Klamath is beginning to show up splendidly, and promises to be one of the best paying claims on the river. It is one of the largest bars, and the pay gravel is believed to be 20 ft deep, affording plenty of rich mining ground for many years to come. A short time ago the miners came upon a high wall of black porphyry, beyond which good pay was found, realizing upwards of $40 to the bucket.

NEVADA.

WASHOE DISTRICT.

YELLOW JACKET.—The north lateral drift on the 3000 level was advanced 41 ft. Present length of same, 329 ft from the switch. North lateral drift on the 2328 level has been run 21 ft, making the present length of same 129 ft from the north winze. The ground is quite hard again, with less water. The north winze is this day 242 ft deep on the slope, having sunk the same 27 ft since last report. Ground quite hard. Sixteen ft more on the slope will reach the 3000 level.

CHOLLAR.—No underground work has been done for this company since last report.

CON. VIRGINIA.—Opening up winzes and connecting drifts with Con. Virginia old shaft to improve ventilation on the lower levels.

UNION SHAFT.—Repairing 1600 drift to Sutro tunnel connection, and completed laying extra line of pipes in same. Also cutting out bob pit at 2600 station.

CALIFORNIA.—Are opening up winzes, and connecting drifts with the Con. Virginia old shaft to improve ventilation on the lower levels. The 2700 level joint Ophir cast drift advanced 24 ft.

ALTA.—During the past week the east drift has been extended 44 ft; total distance from the shaft, 115 ft. The rock is hard, and the heat so oppressive that it will be necessary to put in another Baker blower for ventilation.

POTOSI.—The east crosscut on 2400 level is in a distance of 31 ft, and shows no water. The material passed through during the past week was hard porphyry. The underground work for this company is done by the C. N. S. men, for which we settle each month

SIERRA NEVADA.—The 2500 level east crosscut No. 2 extended 16 ft; east crosscut No. 4, 33 ft; main north lateral drift, 30 ft; west drill hole, 192 ft. The 2700 level joint Union Con. east drift extended 15 ft; Joint Union Con. west drift, 20 ft. Joint Union Con. east winze cleaning out bottom.

SAVAGE.—The Savage folks are extracting ore from the 1640 level, and from the old Potosi tunnel level, the bulkheads in the Chollar-Norcross-Savage shaft having been removed.

OPHIR.—The Ophir Co. have so far extended the old upper tunnel that it is now about under the Ben. Rowe vein. They are also sinking on the vein from the surface.

ITEMS.—There is about 400 ft yet to run to connect the west drift from the Joint Union Con. and Sierra Nevada winze on the 2700 level with the east drift from the Union shaft. Work is vigorously prosecuted from both ends and a progress of 40 ft per week is made. The east drift is intensely hot, which makes work necessarily slow. The Joint Ophir and Mexican east cross-cut on the 2900 level is being advanced in a favorable formation, although no assays are being obtained, as currently reported. The middle mined in assuming an increasing shape, and have now the invaluable aid of the finest system of pumping machinery ever constructed. In the Overman, Belcher and Crown Point they will very soon be ready for cross-cutting and other prospecting operations, while at the Alta they are going for their vein on the 2150 level as fast as powder and muscle can send a drift. It will take at least 6 weeks to complete the repairs in progress at the Hale and Norcross. Intense heat retards operations in the north end mines as well as in the middle or water mines. The Gold Hill group of mines are much cooler. At the Gobiston shaft the bob and tank pits are completed, and a double line of pumps will be put in to the 2100 level this week. In the Alpha and Imperial both are at work on the 2800 level. There is talk of resuming work in the Quinn mine.

BERNICE DISTRICT.

A NEW DISTRICT.—A mining district, called the Bernice, has been created in Churchill county, some 60 miles northwest of Austin. The principal ledge is said to be 8 ft in width, carrying free milling ore, from which assays have been made running from $50 to $250 to the ton. Several parties from Austin have visited the district, and speak enthusiastically of the prospect, says the *Reveille*.

CRABB DISTRICT.

MACHINERY.—*Herald*, Oct. 8: Machinery has been purchased for putting up a mill here. In a trial of the ore, 3,000 lbs yielded 10 lbs of amalgam.

ESMERALDA DISTRICT.

AT CORY CITY.—*Herald*, Oct. 8: There are about 35 men working at this place. The city boasts of a store, blacksmith shop, lodging-house, boarding-house and a saloon. The Hicks 8-stamp mill is getting away with 6 to 10 tons of Bay Injun ore daily. The ore has to be hauled about three-quarters of a mile. Toby Crossman and E. L. Buckingham are down on their claim about 100 ft, and have a fine prospect. Messrs. Young, Smith & Co. have a tunnel run about 60 ft on their property, and have struck a ledge of good paying ore. There are many other claims being worked, and the prospect for a live camp is good.

THE JENKS & GROSS MINE.—Tunnel in 180 ft, and a shaft sunk 30 ft on the ledge. Ledge is now some 5 ft wider than the shaft. Crosscutting will be commenced in a few days to ascertain the exact width of the ledge. Three assays went $130, $100 and $140, principally gold; 20% silver.

MORTITE.—Three shifts at work on the tunnel here, which will cut the ledge in 20 days; also making a good showing in the uppermost workings of the mine, running drifts and upraises, finding magnificent ore.

EUREKA DISTRICT.

THE WILLIAMS MINE.—*Leader*, Oct. 7: Connection is being made between the 300 and 360 levels of the Williams, in order to have better ventilation. The mine looks well, and new ore bodies have recently been uncovered. Parties in London have made inquiries lately concerning the Williams, with a view of purchasing it, but the owners, Messrs. McNaughton & Taylor, manifest no disposition to sell.

EUREKA TUNNEL.—*Sentinel*, Oct. 8: Good progress is being made on the ore body recently found in this property, though its full extent is as yet a matter of conjecture. So far the improvement is very encouragiug. The work of development, however, is progressing slowly, and it will be some time yet before the new find is fully explored.

GRANTSVILLE DISTRICT.

REPORT ON THE ALEXANDER.—*Bonanza*, Oct. 8: Supt. San Pedro reports mine looking as well as usual. Chloride stope between No. 4 and 5 levels is furnishing about one-half the amount of ore requisite for the mill. Stopes on No. 6 continue to yield usual quantity of ore. Are running a drift on this level northward along the supposed foot wall, and under the No. 5 ore body, which is showing splendid ore as far as run.

THE BROOKLYN.—No. 3 level going southwest was advanced 23 ft since last report, making the total length to date 105 ft; will have some 20 ft further to run this drift before cutting the No. 2 ore body. The ore stope on level No. 2 keeps improving in size all the time, and will produce a large amount of high-grade ore.

PIOCHE DISTRICT.

A LONG UPRAISE.—Ward *Reflex*, Oct. 3: The upraise started in March past to connect the old upper works of the Martin White has been completed. It is 700 ft long and settles the question of ventilation, enabling further developments to go on with comfort. The air comes from the mouth of the main tunnel, a distance of about 4,000 ft, with a rush and a roar. A chute is to be put up in the upraise, and all the ores and waste will be put through it to the main tunnel. In addition to developing the ore-body where the raise comes out, it is also the intention to do some prospecting along the line of the raise where several bodies of ore have been passed through.

ARIZONA.

COPPER MINES.—Tombstone *Epitaph*, Oct. 6: Three mines, which are situated in Cochise county, about 50 miles by wagon road, east from Tombstone, are yielding immense quantities of rich ore. The principal mine in the group, the Copper Queen, turns out 25,000 lbs of copper ore per day, on an average, some days running as high as 20,000 lbs, and others falling below the first figure, but making an average of 25,000 lbs or 375 tons per month. September was the first month that both smelters have run, and then not up to their full capacity, owing to various causes, and yet 1,806 tons of ore was smelted, producing 320 tons of copper. The entire product of the mine is shipped to the Ansonia Brass and Copper Works, at Ansonia, Con. As the metal is produced here at a cost of about 8¾ cents per pound, the profits realized are large. Since its incorporation, in New York, the company has paid monthly dividends of 1% on the par value of the stock of $2,500,000, thus making $25,000 per month. From this time on the dividends will be doubled, and there will be $50,000, or 2%. The 80,000 tons of ore now in sight is equivalent to 17,500 tons of copper, which should, at present prices, net the company $2,975,000. There are two 20-ton smelters at work day and night turning the crude ore into bars of what is technically known as black copper, which is 97 to 98 fine, averaging 97¼ fine.

THE Neptune company also own a valuable group of mines, and have about 300 tons of ore on their various dumps. Their smelter is located upon the San Pedro at Hereford, and will be ready to start up in the course of a week or 10 days. There are a large number of other locations within the district, many of which show good prospects.

BRITISH COLUMBIA.

KOOTENAY DISTRICT.—Spokane Falls *Chronicle*, Oct. 5: The construction of the Northern Pacific and Canada Pacific railroads, the one running a short distance to the north and the other to the south of this district, is likely soon to impart to prospecting and mining operations there a great impetus. As is well known, the country abounds in rich placer mines from which only the cream was taken by the first crop of miners, who, entering it along from '59 to '61, remained only long enough to wash the surface gravel; which done, they departed, leaving the country nearly deserted for the next 20 years. Knowing well that they had not exhausted the placers or even reached the richest portions of them, a number of the early adventurers into that region have returned during the past few years and taken up what they considered some of the most promising grounds and are now opening up and preparing to work the same. As the deposits they are now going after in most instances lie deep, it will require some capital and labor to reach and remove them. Hence, while the prospects are exceedingly encouraging, actual production must necessarily be postponed for a little time, deep shafts, and in some cases tunnels being required to open up the claims. Among the best managed and most promising of the new enterprises is that of the Kootenay Mining Co., organized to work the bed of Perry creek, known to be extremely rich in gold. The company, while incorporated under the laws of Washington Territory, have procured from the Legislature of British Columbia a long lease of the ground, which they are now opening in a thorough and systematic manner, the work being prosecuted with such energy that it will probably be completed before spring. When finished the gold that will be taken out here will astonish every one but these old timers themselves, who expect, and, in fact, may be said to know, that they will each and everyone realize from the first season's work a very handsome fortune, such result being made certain by the big prospects obtained from the several shafts sunk to bedrock. This company, being made up in part of practical miners working harmoniously together and financially strong, are in the best possible condition to make a success of the undertaking, and such is the confidence felt in the outcome of the enterprise that the company's shares are sought after here among all classes of our business and moneyed men, who would readily buy them at a considerable advance on their par value, were there any for sale. We hear of other mining schemes likely to be set on foot in that quarter, if some of them have not been already inaugurated. Prospecting for both placers and quartz will, no doubt, be very active throughout that entire region the coming spring, some gold bearing ledges having been found and located already.

COLORADO.

HAVERLY GOLDEN GROUP.—Denver *Tribune*, Oct. 5: The mines and the stamp mill of this company are on Bear creek, an affluent of the river San Miguel, which discharges its waters from a precipitous gulch, which cuts through many gold-bearing veins of the specially famous San Miguel gold region. Mr. Haverly and his associates invested in these properties over 2 years ago, and since have done development work sufficient to warrant the erection of a stamp mill, which, after making a test run on ore now on the dumps, will shut down for the winter. It is intended to add 10 more stamps, to be in readiness for next season's operations.

NORTH PARK.—The Rocky Mountain Co. own here several valuable mines, on some of which the work of development has already been commenced, and will be pushed with all the vigor and enterprise characteristic of the gentlemen at the head of this organization.

VARIOUS MINES.—Thursday of last week the Ute turned out 30 tons of milling ore, and on Friday sent to the surface full 50 tons. The San Juan Chief, near Mineral Point, is developed by a 20-ft shaft, and shows 2 ft of gray copper. The Silverton *Herald* says: "As the present writing we know of at least two smelters that will be erected in Silverton next year, which will give employment to a large number of laborers, and also a sale for the thousands of tons of ore now on the dumps of our mines. Indeed, from the present outlook Silverton will be the boss mining camp in the State before two more years roll around." Miners and mine owners of Silverton are laying in large supplies for the winter, which is a good indication that the mines of that district are going to be worked extensively between now and spring.

IDAHO.

SMELTER NEAR HAILEY.—Wood River *Miner*, Oct. 4: The smelter at Marshall gives employment to 15 men, ore and charcoal being plentiful. The dust arrester works nicely, making a saving of from 2½% to 3% net. The company is smelting ores from the following mines: Minnie Moore, Bellevue; Washington, Deer creek; Star, Hailey; Elk Horn, Warm Spring district. These ores average about 100 ozs to the ton, the smelter turning out 10 tons every 24 hours. During this last run of 15 days the company has shipped over 100,000 lbs of bullion.

KETCHUM.—The new smelter near this town is about ready to start up, and when in operation will make a great difference to the adjacent country

CRUSHING.—The Rising Sun mill, on Shaw's mountain, 12 miles from Boise city, has just finished a crushing of 134 tons of silver rock with good results.

DAKOTA.

VALUABLE PROPERTY CHANGES HANDS.—Black Hills *Times*, Oct. 6: The Fort Meade silver mining company today purchased the Red Cloud mine at Galena, in Bear Butte district. This is undoubtedly one of the most valuable mines in the Hills, and the Fort Meade company is displaying rare energy in that they have not only purchased the mine, but have shipped all necessary supplies and secured the services of the former owner of the Sitting Bull lode, who will immediately commence work and ore shipments to Omaha. Omaha will soon appreciate the Bear Butto district.

THE GUSTIN.—Black Hills *Times*, Oct. 5: This mine is being continually and profitably operated. The 25-stamp mill is running all the time, and the 20-stamp mill that is now undergoing repairs will soon start up again. In the spring this company will have a new 60-stamp mill in operation, and it will then be one of the foremost bullion-producing mines in the Hills.

THE PENOBSCOT CO.—Has a full force of men at work in its mine, day and night shifts, developing and opening up, and besides keeps the mill running all the time.

NEW MINING CENTER.—There is reported quite a mining excitement on Clark's fork, Yellowstone valley. Big assays of both gold and silver ores attest that there is some foundation for the rumor, but as the find is on the Crow reservation, no active work can for the present be done; but as the miners are near the route of the Northern Pacific railroad, an effort will at once be made to induce Congress to treat with the Indians for the title to this land. This is little doubt but this effort will prove successful, as it will receive the support of not only a numerous mining community, but also of the railroad company, who have a large interest in having the country opened up to the miners. The mineral resources of Montana are next in importance to the agricultural interests of Minnesota and Dakota, and the Northern Pacific will do all it can for their development. There will be but little trouble to secure the cession of these rich mineral lands from the Crows, unless officious intermeddlers shall make trouble by misrepresentation, for the mineral belt is absolutely of no value to the Indians for any purpose, as there is neither grazing or hunting on their sterile sides and snow-capped peaks. The mineral is found from 7,000 to 10,000 ft above sea level, and is largely in tellurium formation.

THE Western M. Co. own a group of mines, some of which have been worked and yielded fine ores, but operations were suspended on them after they were found to be on the reservation. Besides very satisfactory assays much ore from this region has been submitted to working tests with equally good results.

BLACK WARRIOR.—Twenty tons of ore from this mine has just been shipped to Salt Lake for reduction. This vein is 6 ft thick, and the lowest assay yet made of the ore yielded $600 per ton, and they think this mill will return from $1,000 to $2,000 per ton when they have worked it on the vein, the assays having all been made from surface ore.

WAR EAGLE.—The War Eagle, owned by Ponsford & Patton, is of the same character of quartz as the Black Warrior. The miners have developed the vein in every direction, and the promise of the outcropping is well sustained throughout.

THE Silver Zono yields free gold, and has yielded as high as 500 ounces of silver to the ton. The finding of a piece of free gold led to the location of this mine.

THE so-called Bowlder mines are placer mines, and were in the hight of their development when the Nez Perces, under the fierce chief, Joseph, went through the camp in 1870, and cleaned out the outfit. Hardly had the remnant of the camp returned when the Arrapahoes descended upon and killed 20 of them, and since then the miners have simply sought to hold their claims until they could be protected in operating them, after their titles shall have been clearly established. Some of these were discovered and operated after a crude fashion as much as 18 years ago. They promise to pan out well under favorable development. The advent of the railroad and Eastern capital will tend to put a new face on affairs and bring them out right very speedily.

THE Bear and Crevice, also placer, are located on the Yellowstone at the mouth of Gardiner river. This is a free gold lode, discovered in 1804, and at one time worked by a camp of 13 men, all of whom were set afoot by a raiding band of Indians, who stampeded their horses where they thought they had them securely cached at the head of the creek. The Legal Tender is owned by Stoner, McLaughlin & Co.

GUNDORF.—The Gundorf is owned by the Gundorfs, Hartman, Cannus & Fisher, and has yielded $3,500 per ton, which is fine pay dirt. The dust is cashed at Bozeman by the hank, and miners regard this class of mineral with great favor because it can be so easily converted into cash. These mines will be worked for all they are worth when titles have been perfected and the Northern Pacific shall have been constructed along the upper Yellowstone within easy access of them. Others will be discovered and developed, for these mountains are full of pay dirt and rich mineral.

MONTANA.

THE MOULTON MILL AND MINE.—*Inter-Mountain*, Oct. 4: The mill of this company is finished, and over 1,000 tons of ore on the dump and in the ore-houses. The only delay in starting the mill is the failure of the contractors having the contract to bring in the water by the 4 mile covered flume. The same is now completed to within 3,000 ft of the mill, and will be in within the next 10 or 15 days. As soon as the connections can be made, the mill will be ready to start crushing. The sudden rise in price and the scarcity of lumber renders it impossible to secure lumber fast enough to finish the flume. The mine is looking in splendid shape, and opened in such a manner that at any time the mill starts it can furnish ore enough to keep it running to its full capacity At present only such ore as is necessary to remove in order to develop the mine ready for a heavy production of ore is being raised. The 400-ft crosscut is nearing the rich body of ore found on the 200 level. The crosscutting on the 500 level is being pushed with as much speed as possible, and as soon as the vein is cut on the 500 level, the work of sinking to the 800 level will be resumed.

UTAH.

ONTARIO CO.—Salt Lake *Tribune*, Oct. 10: A new 3 compartment shaft is being sunk on the Last Chance claim belonging to the Ontario Co. Two of these compartments are for hoisting and one for pumping, the shaft being 21x8 ft. The machinery is very massive, weighing over 500 lons, including the pump and engine. The shaft, now down 160 ft, will connect with the 600 level. The drain tunnel driving to connect the mine with the mill is now in a distance of some 280 ft. When finished, it will be nearly 1 mile in length, and it is the present intention, if possible, to finish it within 2 years.

VARIOUS MINES.—The Barbee & Walker mill was started up several weeks ago and has been running steadily since. The ore deposits are improving, the extreme north stope on the 4th level north showing a face of ore 14 ft thick. Work continues on the Lead's mine with a moderate force, principally upon ore. There is upwards of 500 tons ready to be landed on the mill floor as soon as the repairs are completed In the Stormont mine a strike is reported in the 3d north drift. The face of the winze now sinking to connect with the 3d and 4th drifts south shows a stream 2 feet ledge with rich ore. At the Utah, drifting for the vein on the 340 level is being pushed ahead. It is expected the vein will be cut about 30 ft from shaft. The Empire has discontinued the work of tanking for the present. They expect, however, to resume operations about the 1st of the month. The building of the hoisting works still continues. The Tidal Wave has abandoned its old shaft on account of bad air, and a new one has been commenced. At the Pilgrim mine 45 men are employed. They have about 100 tons of ore on the dump, and will ship to the Park City smelter as soon as the new grade is completed. The Pinyon is a fine and well developed mine, and were the pending litigation at an end, would easily add one-third to the present bullion output of the camp.

UTAH ANTIMONY.—The first shipment of antimony from Utah to Baltimore, which upon being worked was found to yield from 60% to 65% of antimony, should mark the beginning of a new branch of business. Central Utah has immense deposits of this mineral, and there is certainly no longer any necessity for importing it, as we have been doing for years, and paying a duty of 10% ad valorem.

THE GREAT BASIN MINE.—This property under the management of Genl. P. E. Connor, is now in splendid condition and making a large and profitable bullion production. The daily output of ore amounts to about 60 tons, all the engine can hoist, a fact that admonishes the management of the necessity for a more powerful engine and a new or enlarged shaft, as the stock of ore is ample and will bear heavy drafts upon it for a long time.

WASHINGTON.

SILVER ORE.—The press of this Territory contain accounts of rich silver ore having been discovered in the vicinity of Mt. Adams, one of the lofty peaks in the Cascade range. Some of this ore is reported to have assayed as high as $66 per ton.

RESPONSIBILITY OF ENGINEERS.—Investigation into the recent Morelos accident in Mexico, where a train plunged through a bridge into the river with terrible destruction of life and property, has resulted in a verdict of the department of public works finding the chief engineer of the company and the government engineer responsible, and steps have been taken to proceed civilly against the company, and criminally against the engineers. If bridge builders and engineers were always to be held responsible, criminally, for accidents resulting from failure of their structures, the effect might be to increase the cost of many of the structures unnecessarily, but it is doubtful whether it would be just or serve any good purpose. Men do not build bridges intending to have them fall.

COLORED children having entered the public schools at Galena, many of the white children went home, and two of the School Board resigned.

Academy of Sciences.

Want of epace prevented onr reporting tbe reguler meeting of the Academy of Sciences. Dr. Behr was in tbe chair. Wm. Robinson, Principal of the Hamilton Grammer echool; Andrew J. Hatcb, Surveyor-General of Nevada, and F. S. Donty, Secretary of the Pacific Improvement Company, were elected resident memhers, Mrs. John R. Sargent was proposed for memherehip.

Animal Foseils of Santa Clara County.

Among the donations to the mnsenm were the following: From L. P. Alexander, of Santa Clara, presented throngh A. W. Sexe, M. D., a fragment of an entire cross section of a fossil elk horn, thrown up Angnst 1st, through the month of an artesian well, 487 ft. deep, bored on the farm of Mr. Alexander, near Lawrence station, on the Southern Pecific railroad, ahout a mile and a half northward on the Alvieo road. The diemeter of the bore was 10 iuches, located in a deposit of sandy clay and gravel, nnderlying a stratum of clay 20 ft. thick. The accumulating numbere of similar animal fossils, found at various depths, in the alnvium of Santa Clara valley, in artesian wellborings, or in the material ejected by the outflow of these wells, are rapidly increasing in interest to the ecientific student, as bearing directly on the now almost certain fact of remote geological subsidences and local elevations about the Bay of Sen Frencisco. It is pretty generally accepted that the Golden Gate was opened by a rupture during some such cataclysm, and eome incline to the helief that many thousand yeare ago the Pacific ocean extended to the foothills of the Sierra Nevada mountains. Goat island, in our bay, and all the stratifications of the exposed parts of monntains, appear to indicate local elevations bnlged up by side pressnre. A very large and perfect stone Metate, with its grinding stone, nsed by the Indians in grinding ecorne and grass seed, wee presented by John Berker, of Sumner, Kern county, Cel., which wae dug up in that neighborhood. Mrs. Mary Melrose donated an anoient stone pestle, dng up in Sen Jose.

Indian Trout Hooke.

B. B. Redding presented an Indian trout hook and line, nsed hy the Shoshoncs. He described how they nsed these very ingeniove contrivences, curious as showing the ingenuity of man in procuring food. The hooks are mede of eharp fishhone, back of which is placed a willow stick to act as a epring to keep the hook in the fish's mouth, answering the eame purpose as a berb on steel hooks used by us. He then described certain large arrow heads, of which there are three in the Academy's mnseum, and said he had jnst leerned their nse from the practice of a Shoshono chief. They were nsed as the head of the officiel speer of the chief of the trihe, and were the emblem of his anthority. They were only nsed when the trihe was celled together in council, and were affixed to a staff usually about 7 ft. high. They are rarely found. Prof. Cope has two, the Smithsonien Institute hes six, and the Harvard museum three. He knows of no others. They are best described ae the emblem of a chief, and are not "fleshers," as eome have supposed. Varioue intereeting donations were then made to the library, inclnding a eet of Mexican meteorological reports of their Netional [observatory, which may well repay a carefnl study.

Analysis of Recent Arctic Advices.

Charlee Wolcott Brooks heing called upon to explain to the Academy the letest reports from the various Artic expeditions now at the North, gave a concise synopsie of the verious details of Arctic newe which have thns far heen received this autumn. He illustrated on a large map the course of the recent cruise of the *Corwin*, and Capt. Hooper's gallant exploit in landing on Wrangel Land. He sifted and compared the various stories given by native Tschuktchie and Innuits, in Siheria on the Russian coast and in Alaska on the Americen side, and expressed the belief that they referred to either or both the whaleships *Vigilant* and *Mt. Wollaston*. He ehowed very plainly that if the *Jeannette* ie succeeding in what she hee undertaken, she mnst necessarily he far north of where any vessel from which we have since heerd could posiihly have commnnicated with her. We have no reports from any part of the Artic hasin farther north than Point Barrow on one side, and ebout the latitude of Herald island on the other. The *Jeannette* should be at least eix degreee farther north, and may be working through across the Polar region, and may eventually come down along the coast of Greenland on the Atlantic side. Thie was her aim, and the brave De Long and his heroic band will eurely do it if their most earnest efforte can ensure success. The *Jeannette* was abundantly fitted for a three years' cruise, with provisions enough to eke out five years. At the date when we

Last Heard from the Arctic,

Namely, Ang. 16, 1881, it was only one year, 11 months and 12 days since the *Jeannette* wae last seen, Sept. 4, 1879, eteaming northward, near Herald island, along a channel of water, heading for the Pole. We cannot think ehe wintered the firet winter eouth of latitude 78° north, while Herald ieland ie in about 71¼° north. Should any inquire why relief veeeels have heen eent, under these circumetancee the answer ie very clear. They were sent to he prepared and ready at the point of exit from the Polar ice along the southern edge of the ice peck to render assistance in case of any accident to the *Jeannette*, in which event her crew, well snpplied with dog sleds, doge and provisions, would have made their way southword on tho ice and have heen rescued hy the relief vessels. It is well nnderstood hy all scientific societies that anch relief vesseleshould he on the spot reedy and prepared to assist at any time a vessel, which, like the *Jeannette*, has heen pnt into the pack hy her commander, with a view of advencing as far toward the Pole as may be possihle. Other nations have edopted a like policy. Mr. Brooke then gave the experience of the steamer *Proteus*, which took the Greeley party to Lady Franklin hay, in latitude 81° 40′ north, and after landiug them without any material delay from ice, retnrned to St. John'e, N. B., reaching there after an ahsence of only 70 days.

All Accounte Agree

Thet along the track taken by the *Jeannette*, and where ehe aims to come out, the season hes heen a most nnusnal and exceptionally open one, and the Artic hed much open water for two months last winter. This was also true on the coast of Greenland, elthongh ahont Nova Zemhla the eeason was severe. All things seem to favor the *Jeannette's* progress northward, and Mr. Brooks concluded hy expressing his firm helief that she will he heard from hy next July, perhaps on this eide, hut quite as likely on the Atlantic, which will he the glorious echievement for which her voyage was planned and undertaken. After describing the ocean currente this season obsnrved in the Arctic, allusion was mede to a marine buoy which got adrift from the Amoor river, near De Castrie's bay, in Siheria, having on it Rnssian characters, which had recently heen reported to have heen cast ashore upon Vancouver Island, on our coast, hy the action of the Kuro Siwo, or Japanese Warm Stream.

Metallurgy of Nickel.

At the recent exhihition of the Germen patents and designs the metallnrgy of nickel and cohelt wes illustrated in an interesting manner by Fleitmann & Witte, of Iserlohn. Dr. Kollmann descrihes it as followe:

It is only within a few years since the discovery of pure malleable and weldeble nickel hy Dr. T. Fleitmann, that nickel has entered the renk of those metale which are technicelly employed on a lerge scale. Previously, only the alloys of nickel with copper end other metals could he easily wrought, while pure nickel could he neither hammered nor rolled. The reason of this was thet pure nickel absorhs (occludes) gases while melted (Fleitman thinks it is carhonio oxide), and the nickel cannot be worked nntil these gases are removed.

Fleitmann's procese for meking nickel malleable consists in adding a very emall trace, only one-twentieth of a psr cent., of magnesium, which is introduced in the form of a har into the liquid nickel while in the crucihle. This small percentage of metallic magnesium renders this brittle metal perfectly malleeble, and it can even he welded. Magnesium is well known to oxidize very easily (at high temperatures), and hence eerves to remove these injurious gases. (Would not phosphorus accomplish the seme end?)

The extraordinary tecbnical importance of the new discovery (which is alreedy patented in all countries) is evident at once. Formerly, alloys with comparetivly only a little nickel could be used, say, for coin. The German 10 pfennig pieces (like the American 5 cent piece) contain only 25% of nickel to 75% of coppsr. Now, on the other band, we can have pure nickel cast in any desired ehape, and also forge it and roll it like iron or eteel. We mey, indeed, assume with tolereble certainty that if Fleitmann's method had heen known 10 years ego we Germans would not have been pestered with our unhandy little 20 pfennig silver coins, for much more convenient ones could have heen stamped from pure malleahle nickel. Pure nickel, in addition to its melleability, possesses the great advantage that it does not lose its luster in moist air and ie nnaffected hy organic ecids, while its alloys, we know too well, gradually lose their luster and tnrn reddish.

Fleitmann, in his very interesting investigation, also made the discovery that pure nickel treated with a very little megnesium, becomes weldable just like iron, and upon this he founded a method of welding nickel to iron. Thie discovery has gained very considerahle importance, eince we are now ahle to weld plates of nickel on both sides of the iron or eteel, instead of merely depositing ou it a thin coating hy electricity.

The question of welding, which is not yet settled in the metallurgy of iron for Bessemer metal, for example, may perhaps he solved in a manner similar to that in which Fleitmann solved it for nickel. Its importance technically and economically can hardly he overestimated. Nickel made hy the new process with magnesium has a resemhlance to carbureted, malleable iron.

Kollmann made a series of teste of strength with Fleitmann'e nickel, and arrived at a surprising result, namely, that the elasticity as well as the absolute strength correeponde exactly with thoee of medium hard Bessemer steel.

The expansion by rolling aud forging of the two metals is the eame, eo that they can he rolled together.

Kollmann then givee some of the nnmerical resulte of his teets, which we omit, hnt they go to show that the physical properties of nickel and iron are very analegous, eo thet the thought arises that perhaps nickel is, after all, only an allotropic state of iron!

Since nickel and steel expand equelly, blocks of nickel can be welded on hoth sides of an ingot of steel, and the whole rolled out into eheete of any desired thickness already covered with nickel. Iron wire covered with nickel conld he drawn out jnst like ordinary wire. Another advantege is that the welding as well as the melting temperatnre of steel and nickel is close together, eo thet the nickelized steel can he welded as hefore.

Cobalt can be rendered malleable and weldahle in the eame manner, *i.* e., hy the addition of a little magnesium.

Fleitmann has also discovered that not only can nickel and cohelt he welded on steel and iron so as to form nickel-plated wire and sheets, hut that it can he welded on to tbe alloye of copper and nickel, which can he rolled at a very high temperatnre. In this operatiou the metals to he welded are surrounded with thin sheet iron, which is afterword dissolved off, or is heated in an eir-tight apperatus. In this way, too, sheet iron can he comhined with elloys of copper and nickel hy welding.

To prevent articles made of nickeled eteel or iron from rusting on the cut eurfaces, the iron heneeth is dissolved awey et the edges with dilute acids, and the projecting nickel then hammered down and welded over it. In Birminghem, H. Wiggin makes nickel malleahle hy adding 2% to 5% of mauganese.

The State Bag Factory.

The State enterprise looking toward tbe cheep production of grain hags by the labor of conviete at San Quentin is progressing, and Gov. Perkins' proposition to cheapen burleps, employ convicte, and still not come into competition with legitimate local menufacturing enterprise, will soon he put to a prectical test. Those who have the enterprise in hand are quite confident that the convicts can be made self-supporting, and at tbe same time begging material cheapened, which will be a merited hoou to our grain growers. If everything snceeeds as now anticipetcd, we may ere long he growing jute, and then the great drain for hegs and burlaps paid to the manufactories at Dundee and Calcutta will be stopped.

For the jute-meking effort it was necessary to bnild new buildings, and the main pert of the work wes done by the convicts. A reporter for the *Chronicle*, who lately visited the prison, gives a description of the new jnte factory, from which we shall take the leeding points: The buildiog is of enormous proportions, and is designed from the letest approved plans submitted as hest adapted for heevy mechinery running with strong vibratory motion. Ite ground plan is a parallelogram for the main building, which is 265 ft. long, extreme length, and 153 ft. wide, extreme width. The floor in preparation is solidly packed and tamped with the hest quality of gravel and seud, hetween closely-leid heavy timhers of redwood, and then cemented into a smooth, heevy concrete with Portland cement, meking it is as solid as if of stone foundation. The building is of one etory, with 16 ft. in the clear; from the floor to the hottom of the joists above is a succession of eight-gable roofe, each of the seme width and running laterally the fnll width of the building.

Each roof is covered with tin, and has on top a gable line of ventilators 3 ft. high by 5 ft. wide, running the entire width of the building. On the north side of each roof from the hottom of the ventilatore rune a sky-light 5 ft. wide throughout the entire length of the roof. The huilding to begin with ie framed from selected pine and redwood, and eo bracod and trussed according to tbe latest eccepted plane from Dnndee, Scotland, ae to deetroy the tendency of the machinery to vihratory motion. There are within the building, as sopports, 126 messive uprights of pine, each properly fitted to cross pieces, besides heing fastened firmly within the concrete, and all to he covered with tin to gnard against fire.

The machines—menufactured in Leeds, England, and embracing a complete symtem of 100 looms, with eoftening, breaking, damping, twisting, werp and cop winding, spinning, dressing, measnring, sack-cutting and calender machines, total 148—are all at San Quentin in perfect order, even to minute details of extras belonging to such thorough and complicated machinery. Although the building, as just described, is independent in itself, constructed with a view to ite heing entirely free from vihration, it is inclosed by massive hrick walls, 25 ft. in hight, and with piers at each 15 ft. snpporting lateral heavy timhere holding the line shafting, thns adding to the eolid character of the structure. A helt chamber, to regnlate the revolntions of the various lines of shafting from which the different machines are run, starts from the flywheel on the west eide and runs the full length of the building, having a full width of 7½ ft. within the huilding.

In addition to the main bnilding an engine and boiler-room ie heing erected adjoining, with a length of 60 ft. hy 40 ft. wide. The ground for the same has heen excavated to a depth of 12 ft., and ie being filled in with solid maeonry to form a thorough support for the engine and hoilere, which are of maseive pattern. The motive power for thie vast etructnre consists of four eteel hoilere, each 16 ft. long by 53 inchee wide; a low presenre engine of 480 horse-power, having a 30-inch cylinder with a 60-inch stroke. The fly wheel drivee tbe main belt, which has a widtb of 42 iuches. The wheel itself is 18 ft. in diameter end has a full weight of 20 tons. The factory is expected to he in complete working order by Jenuary 1, 1882.

Dissenting Opinion in the Debris Case

We gave lately an abstract of tbe decision in the "slickens case," mentioning merely that a dissenting opinion had heen filed by Judge Sherpstein. As the dissenting opinion brings forward some significant points, we give it in full:

I dissent. It eeeme to me that most of the grounds upon which it is claimed that the "act to promote drainage" is unconstitutional cennot he considered in this cese. Courte will not listen to an objection made to the constitutionelity of en act by a party whose right it does not affect. A stetute is assnmed to he valid until some one complains whose righte it invedes. (Cooley's Const. Lim., 163.) In the language of the Code, "Every action must he prosecuted in the neme of the real perty in interest." This ection is brought hy the people of the State, and if the provisions which effect them aro constitutional, they are not necessarily affected hy the other provisions of the act, even thongh they be unconstitutionel. "A statute may contain some euch provisions, and yet the same act, having received the senction of ell hranches of the Legislature, and being in the form of law, may contain other useful and salutary provisions not ohnoxious to any just constitutional exception. It would he inconsistent with all just priociples of constitutional law to adjudge these enactments void beceuse they are essociated in the seme ect, hut not connected with or dependent on othere which are noconstitutionel." (Id. 177.)

I know of no provision of the Constitution, and am not advised that it is cleimed that there is eny, to which this act, so far as it provides for the reclemetion of overflowed lands, the rectificetion of river courses and the impounding of debris, at tho expense of the State, under the direction of commissionere end directors, named in the act, or whose appointment is authorized hy it, is repugnant. But it is claimed that the power conferred upon the Board of Drainage Commissioners, to fix the houndaries of drainage districts, is legislative in its character, and cennot he delegeted to the executive officers, who, by virtue of tbe act, constitute that hoard. "One of the settled maxims in constitutionel lew is, that the power conferred upon the Legislature to meke laws cannot he delegated by that depertment to any other hody or authority." (Id. 116.) If the act under consideretion attempts to delegate that power to any other depertment of the Government, or to any hoard, person or persons whatsoever, it must be held to be, to that extent, at least, unconstitutionel.

It can meke no difference whether tho attempt is made to confer tbet power upon another department of the Government, or upon persons not connected with the Government. The power cennot be delegeted.

The objection, however, ie not that an attempt is made to delegate the law-making power to a hoard of drainege commissioners, hut that the act authorizes the hoard to estahlish drainege districts, and that that is purely legislative. Whether it he or not, I think, must depend upon the object for whicb suoh a district is formed. If formed for the purpose of levying a especial tax upon the property within it, to defray the expenses of improvements, assumed to he more beneficiel to the inhahitants of euch district than to others, the rule douhtless is thet the Legislature must determine what shall constitute such a district, nnless the nature of the case conclusively fixes it. The object of dividing the State into districts, as steted in the act, is not for the purpose of determning what portions of the State ehall he assessed or taxed to pay the cost of the work. Each district is to he composed of "territory drained hy one natural system of drainage." It seems to me that the formation of districte upon that plan would require engineering rather than legislative ekill.

Whether the designation of officers, commissioners, or persons to determine within what limits lands shall he held to be benefited hy an improvement, would constitute a delegation or legislative power, is a qnestion which, as I view it, doee not arise in this case.

I am not satisfied that the Legislature did not possess the constitutional power:

1. To appoint the officers named in the act as a hoard of drainage commissioners, with power to divide the State into drainage districts and to organize the eame.

2. To authorize the Governor to appoint directore to prosecute the work contemplated by the act, within any snch organized district.

3. To levy a State tax for the purpose of raising money to defray the expenses of said work.

Unless some or all of these provieions of the act are unconstitutional, this action cannot, in my judgment, be maintained.

The prayer of the complaint is:

"First—That said defendants and each of them be onsted from said office of director of drainage district No. 1 of said State.

"Second—That said defendante be perpetually enjoined and restrained from letting any contracte for the huilding of dykee, embankmente or other works for the drainage of said district.

"Third—That eaid defendants be perpetually enjoined from levying any tax whatever upon the property, or any property within said dis-

trict for the purpose of providing funds for the payment of the cost of building works of drainage, or any other purpose.

"Fourth—For the decree of this court determining that said asserted drainage district No. 1 has not been legally formed, and is not a drainage district."

For reasons which I have stated, I do not think that the act is so clearly unconstitutional as to entitle the plaintiff to the relief prayed in the first, second or fourth paragraphs of the prayer. As to the third, I do not think the people of the State can be heard to object to the levying of a tax upon property within the district designated. As before intimated, I think that the legality of that tax can only be called in question by some person or persons who, if its collection be not enjoined, will be liable to pay some part of it.

It is not claimed that the people of the entire State occupy that position.

The conclusion at which I have arrived is, that if all these provisions of the act which contemplate the raising of funds by taxing or assessing any property other than that of the entire State, should be held to be unconstitutional, the defendants could not be ousted from office, nor enjoined from letting contracts, nor, in this action, from levying a tax within the district specified. And if the act be constitutional, to the extent to which I think it to be, it is quite clear that this court cannot hold that said district has not been legally formed.

It is not being clear to my mind that those provisions of the act which affect the people of the entire State are unconstitutional, I think that the judgment of the court below should be affirmed.

The Engineer.

A Big Drainage Scheme.

The telegraph of the 6th inst. announces that a Mexican firm—Mierceles & Co.—has entered into a contract with the Mexican government to drain the valley of the City of Mexico for the sum of $9,000,000.

The City of Mexico is situated near the center of a large elevated valley, known as the Plateau of Tenochititlan. The waters of this valley, which has no natural outlet, are deposited in five principal lakes, situated on different levels. The largest of these is Tezcuco, upon an island in which, mostly of artificial construction, is located the City of Mexico. This lake, which is near the center of the valley, has an area of 70 square miles, and is the lowest of the series. Just north are two other small lakes, and to the south, connected by a narrow strait, is a third—Lake Chalco—covering an area of 50 square miles. These three are only five ft. higher than Lake Tezcuco, upon the waters of which the city is built. The fifth in the series is only 25 ft. above the city. The drainage of this entire valley, which is collected by some 12 or 15 small streams, all finds its way eventually into the lake surrounding the city. The only drainage from this body of water is through an artificial canal 12 miles long, cut through solid rock, in some places 150 ft. deep and 300 ft. wide. The waters of the Tezcuco are salt, while those of the others and more elevated lakes are fresh.

It is presumable that the drainage scheme proposes to remove the water immediately surrounding the city by deepening the present canal.

Success of Underground Telegraphy.—Five years ago it was determined to construct a complete system of underground telegraph lines, uniting the most important commercial and strategical points in the German Empire. The plan also covered the construction of governmental overground telegraph lines, and the erection of buildings for postal and telegraph service, as well as a system of pneumatic pipe mail lines. Five years were allotted for the completion of the entire work, at a total expenditure of $12,480,000. The work is now finished and has cost some $10,360,000. The overhead telegraph lines have been increased in five years from 23,600 miles to 32,913 miles, giving an increase of length of wire of 21,735 miles, while the stations increased from 1,688 to 5,671. The total length of cables amounts to 3,403 miles, including about 23,000 miles of wires. The total weight of iron used in these cables amounts to 24,144,730 lbs. This system now avoids the numerous interruptions to business that formerly occurred from such a great variety of causes as overhead telegraph lines are always subject to. The number of cities and towns thus connected is said to be 221. All the lines thus far laid have proved highly satisfactory in operation. Most of the cables contain seven wires, and a few only four.

Progress of the Panama Canal Scheme.—The manager of the Panama Canal company has recently arrived at New York, from the Isthmus. He states that the work on the canal is advancing rapidly. Twelve hundred men are employed at present in excavating, and he expects to have 8,000 at work by December. The sum of $2,100,000 has been expended on the work already, and drafts are in the hands of bankers of this city for $500,000 more from share-holders in Europe.

Useful Information.

Paper Car Wheels.

The following particulars in relation to the manufacture of paper car wheels, as given in the U. S. *Trade Journal*, will be of interest to many of our readers:—

The paper is straw board of rather fine texture. It is received in the ordinary broad sheets, differing in no particular from those used for straw-board boxes or other similar work. These sheets, as they come from the paper mill, are square, and must first of all be cut to a circular pattern. This is rapidly done on a large table with a knife that is guided by a radial arm that swings freely over the surface of the table from a pivot at the center. A small disk is also cut from the center of the sheet to allow for the iron hub. Being thus reduced to the required shape and dimensions, the paper must now be converted from a mass of loose sheets into a compact, dense body, capable of withstanding the tremendous crushing force to which it will be subjected in the wheels. This is accomplished in the following manner: Ten sheets are pasted together, one upon the other, making a disk about one-eighth of an inch thick. Enough of these disks having been prepared to fill a powerful hydraulic press, they are subjected to a pressure of 1,880 lbs. to a square inch. When removed the disks are hung on poles in a steam-heated loft and left six days to dry. Thicker disks are then made, each formed by pasting together 2 or 3 of those already finished. These are pressed and dried as before, and the process is repeated until a block is built 4 inches thick and of about the specific gravity of lignum vitæ. After each pasting and pressing, six days are allowed for drying, and when the block is complete it is left in a drying-room until thoroughly seasoned. The next operation is that of turning the paper blocks to fit the steel tires and iron hubs. This is done with as much accuracy and in exactly the same manner as if the material worked on were iron or wood. The circumference is turned to a perfect circle of the precise diameter required, a bed or recess is worked out for the web of the tire to rest in, and the edges sharply defined. The block is then painted, and is ready for its place in the wheel.

Common Glue has most enormous strength and adhesive powers if it is good. But to be good it must not have been injured in the making by decomposition, to which the material and glue itself are peculiarly subject. If offensive, it cannot be trusted to hold wood. The strongest known glue is that made from the sounds and skins of fishes, and the strongest of this class is made in Lapland from the skin of a perch. The Laplanders use it in making their bows, which are both strong and durable. In making it their cold climate is greatly in their favor, there a fish skin will begin to undergo decomposition before it can be dried. In making it the skins are put into a bladder, which answers for a water bath, and heated in water until a sort of glue results.

Bleaching Gum Arabic.—The solution of gum is first strained through linen in order to remove earthy matters, fragments of wood, etc., and is then mixed with freshly prepared hydrate of alumina, which must not be allowed to dry up. The mixture is poured upon a linen strainer, and thus a clear, colorless solution of gum is obtained, while all the coloring matters are kept back by the alumina. It is generally sufficient to pour the solution of gum through a moist layer of hydrate of alumina. The more slowly the gum water is filtered the more colorless it becomes. If perfect whiteness is to be obtained the filtration is repeated through fresh portions of hydrate of alumina.—*Muster Zeitung fur Faerberei.*

Liquid Glue.—A product which is better than that obtained by treating solid glue with nitric acid, can be prepared by dissolving good glue in a water bath containing the same quantity of strong vinegar, one-fourth part of alcohol, and very little alum. It is very applicable to such work which does not need a very strong adhesive power. It is always ready for use, and keeps for any length of time. The manufacturers of artificial pearls use it in pretty large quantities; it also serves for fastening mother-of-pearl, horn, etc., on wood and metal.

Destroying Bugs in Mills.—Alum water is recommended for preventing bugs and worms from infesting flouring mills. Take two pounds of alum and place it in three quarts of warm water (or in that proportion), and let it stand on the stove until the alum disappears. Apply while hot, with a brush, to the crevices of the bolting machine and other places that conceal the insects. Alcohol or turpentine should not be used in sponging off bolting cloth, as they dissolve the sizing.

Tests for Iron.—To ascertain if water contains iron, take a glass of water and add to it a few drops of the infusion of nutgalls, or suspend a nutgall in it by means of a thread for 24 hours. If iron be present, the water will become of a dark brown or black color. Prussiate of potash is a still more delicate test for detecting iron. If a crystal or a drop of it, when dissolved, be added to a glass of water containing iron, it will immediately become of a blue color.

A Peculiar Property of Matter.

A great deal has been written concerning the physical properties of matter, and it would seem, so far as our knowledge extends, the subject was well nigh exhausted. Strange as it may appear, there is one property of the most common substance with which the machinist has to do, that has never been accounted for, or in any way alluded to in works on this subject. We refer to that peculiar property of cast iron, by virtue of which, when in the condition of old cinders, pieces of pipe, safety valves, and a multitude of other forms, it manages to get exactly in the way of every man in a good sized machine shop, and at about the same time. Practical men know this to be a fact, and are looking to science for an explanation. It has long been reasonably well established, that in the shop where the custom is to preserve such things, notwithstanding they may be relegated to some particular corner devoted to their preservation, they will find a way to get themselves distributed all over the shop without any very serious delay. It would be a valuable acquisition to our present knowledge to know why this is so. While carrying on the investigation necessary to determine what particular property enables inert matter to get away with the best intentions of proprietors, foremen and workmen, it might be well to conduct it with a view to finding out what property could be added to cast iron, so that it would be possible to get useless scrap from the machine shop and into the cupola.

There is a broad field for scientific investigation, and in a direction where there can be no possible clashing of theory and practice; the latter having virtually withdrawn from the contest.—*American Machinist*

To prevent corrosion on sheared surfaces of nickel or cobalt, plated sheet iron or steel, Dr. T. Fleitmann of Iserlohn, has adopted the following method, which has proved itself very satisfactory: The sheared surface is dipped into strong sulphuric or hydrochloric acid, until enough of the sheet metal has been removed to answer the object; then the remaining plating is folded over by means of a steel rod, and finally the new surface is heated to a red heat in a closed vessel, or by putting it in a charcoal fire, after having been protected by a covering of sheet metal.

Good Health.

The Management of Sick Children.

The vicissitudes necessarily incident to an out-door and primitive mode of life are never the first causes of any disease, though they may sometimes betray its presence. Bronchitis, nowadays perhaps the most frequent of all infantile diseases, makes no exception to this rule; a draft of cold air may reveal the latent progress of the disorder, but its cause is a long confinement in a vitiated and overheated atmosphere, and its proper remedy ventilation and a mild, phlegm-loosening (saccharine) diet, warm sweet milk, sweet oatmeal porridge, or honey-water. Select an airy bed-room and do not be afraid to open the windows; among the children of the Indian tribes that brave in open tents the terrible winters of the Hudson Bay territory, bronchitis, croup and diphtheria are wholly unknown; and what we call "taking cold" might often be more correctly described as taking *hot*. Glowing stoves and even open fires in a night nursery, greatly aggravate the pernicious effects of an impure atmosphere. The first paroxysm of croup can be promptly relieved by very simple remedies: fresh air and a rapid forward-and-backward movement of the arms, combined in urgent cases, with the application of a flesh-brush (or piece of flannel) to the neck and the upper part of the chest. Paregoric and poppy syrup stop the cough by lethargizing the irritability and thus preventing the discharge of the phlegm until its accumulation produces a second and far more dangerous paroxysm. These second attacks of croup (after the administration of palliatives) are generally the fatal ones. When the child is convalescing, let him beware of stimulating food and overheated rooms. Do not give aperient medicines; costiveness, as an after effect of pleuritic affections, will soon yield to fresh air and a vegetable diet.—*Dr. Felix L. Oswald, in Popular Science Monthly.*

Seasickness.

This is caused in great part by the confusing effect which the tossing on the water has upon the brain, and multitudes of ways have been pursued for avoiding or at least mitigating this annoyance. The best plan is to let it have its course and rid the system of that excess of bile which is almost always present in this overeating age; the general health rarely fails to be greatly improved by it, although in very rare cases, perhaps not over one in a million, the patient dies under the effects of the long continued and exhausting retching.

If a person will lie down with the eyes closed, and not allow the head for an instant to be raised from the pillow, there is an almost entire exemption from nausea and other discomforts, but the result of this course is that it will be necessary to keep a bed during the entire voyage. The effort should be to shorten the sickness and get rid of it as soon as possible, and this is best done by not lying down at all, but resolutely keeping on the feet on deck, in the open air if the weather permits, that is, if it be not raining; this requires moral courage and some considerable force of will and character, but it seldom fails to abridge the period of seasickness, some times to confine it to a few hours duration and then the remainder of the voyage can be enjoyed as it ought to be.

The tendency to nausea on ship-board is abated somewhat by any stimulus which acts decidedly on the nervous system, such as chloroform, brandy, opiates, etc. Irritants, such as the strongest spices, abate nausea; so will great mental emotions, in short, anything that draws off the attention of the mind. No person can get seasick if the ship be on fire, nor will a person who is drunk. A brisk purgative is good just before going on board, or a dose of medicine taken the night before. Still, the wisest, most healthful and most expeditious method of meeting seasickness is to avoid all preventives, all medicines, and manfully determine to keep upon your feet and let it do its worst.

The Use of Disinfectants.

Our sprightly cotemporary, the *Star*, of Cottage city, the great seaside resort on the island of Martha's Vineyard, through a correspondent, throws out the following excellent hints on the use of disinfectants. They should be used and understood by every person who has occasion to use such preventives of disease:

In the use of a disinfectant, a double object must be secured. First, the removal of objectionable odors; second, the chemical change of the fetid mass from a state of decomposition and production of noxious gases, rendering it harmless. Probably the least useful disinfectants are those which have powerful odors of their own, as carbonic acid in its various forms, chloride of lime, camphor, etc. For, while these really possess disinfecting qualities, they are apt to deceive by covering up what they ought to remove. Carbolate of lime used upon a putrescent mass will disinfect only where it touches, and unless it is thoroughly mixed with the whole, it will affect only the surface, while, by its wholesome odor, it appears to do far more. Chloride of lime does better, for while there remains in it any chlorine, it will absorb and destroy all foul emanations, but it is soon delinquent and inert. Earth is the best disinfectant. When thrown upon a substance to be disinfected, the salts which it contains slowly percolate through it, and it is chemically changed and rendered odorless and harmless. But the quantity required often makes its use impracticable; so various combinations of the salts of metals have been devised to effect the same result, as the celebrated recipe purchased by the Austrian government and the Gironden disinfectant, both of which are composed of salts from metal bases.

Within the reach of all, however, and certainly effective, is common copperas (sulphate of iron). It can be purchased of any druggist, at from three to five cents per lb., in the crystal, and when used it dissolves slowly in the moisture which it finds, and not only locks in chemical fixedness, the foul-smelling sulphureted hydrogen gas, but it stops fermentation, and thus prevents the formation of microscopic insect or vegetable life, which, taken by the air we breathe, induces fever, diphtheria and other diseases.

Women as Doctors.

At the recent commencement of the Women's Medical College in Philadelphia, some interesting facts were stated concerning the career of the graduates of that institution, which have a direct bearing on the success of women in this field of professional labor. The following are the more important of these statements: Of the 276 women who had graduated from the college in the past 30 years, 32 had died, 31 had given up their profession, and 151 were then practicing. Of the 151 in practice, the incomes of 24 were between $1,000 and $2,000; the incomes of 20 were between $2,000 and $3,000; of 10, between $4,000 and $5,000; of 3, between $5,000 and $15,000; of 4, between $15,000 and $20,000; and of 10, less than $1,000. The average income from practice was about $3,000. Sixty-six were members of medical societies; 51 were married after studying medicine, and 61 before; of 50 who were married, 43 reported that the practice of medicine had no unfavorable effect on their domestic life; with 6 the effect was not entirely favorable; with 1 it was unfavorable; 3 were prevented by practice from marrying, and 5 gave up practice on account of marriage.

These facts make an exceedingly favorable showing for the women doctors, and should be a convincing argument in favor of the practice of medicine by the sex. Indeed, the opposition to them has so materially lessened during the past few years, that it can hardly be said to have any existence since the majority of the medical societies have withdrawn their opposition.

Sheet Zinc is used to a great extent for ceilings in Germany, especially where the beams for the upper floor are made of iron. The use of wood is entirely dispensed with, and excellent decorative effects are produced by stamping, painting and gilding or bronzing a part of the ornaments.

MINING AND SCIENTIFIC PRESS.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Hydraulic System of Draining Mines, 249. End of a Noted Prospector and Explorer, 252. Passing Events; California Mines and Their Occupants, 253. A Convenient Apparatus; Application of Standard Measures to Industrial Processes, 257. Recent Patents, 260.

ILLUSTRATIONS.—The Hydraulic system of Draining Mines now at work on the Comstock, 249. Caliper Gauges: Device for Filtering Liquids, 257,

CORRESPONDENCE.—Mines and Mining on the Klamath—Hydraulic Operations; Tunnel Sites and Blind Lodes, 250.

MECHANICAL PROGRESS.—The Degeneration of Steel; Metallurgical Patents; The Modern Uses of Steel; Friction, 251.

SCIENTIFIC PROGRESS.—Galvanic Deposition of Iron; Electricity Applied to Balloons; The Density of the Earth, 251.

THE ENGINEER.—A Big Drainage Scheme; Success of Underground Telegraphy, 255.

USEFUL INFORMATION.—Paper Car Wheels; A Peculiar Property of Matter, 255.

GOOD HEALTH.—Management of Sick Children; Seasickness; The Use of Disinfectants; Women as Doctors, 255.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meeting and Dividends, 252.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Dakota, Montana, Colorado, British Columbia and Utah, 252-53.

Business Announcements.

Hose Coupling—D. B. Kendall, S. F.
Regular Dividend Notice—Northern Belle M. Co., S. F.
Extra Dividend Notice—Northern Belle M. Co., S. F.
Patent Pick—P. W. Reardon, San Jose, Cal.
To Contractors—New Almaden Mines, Santa Clara Co.
To Shaft Men—New Almaden Mines, Santa Clara Co.
Miners Wanted—New Almaden Mines, Santa Clara Co.
Tonite Powder Co, San Francisco.
Tamalpais Hotel—San Rafael, Cal.

Passing Events.

In mining movements and matters, the week has been uneventful, the great industry throughout all our vast mining domain having been unmarked by other than the nanal advances, mishape and fluctnations. The recent epurt in Comstock shares, having snbserved the ends for which these spurts are gotten us, has subsidsd. While no important developments have lately heen made or are likely to he made on the great Washoe *Veta Madre*, it may intereet the payers of assessments and the losers in the late Sierra Nevada gamble to know that the donkey engine is doing its work bravely on the "Burro" ledge, and that all the pumps along the "great non-metalliferous," from the "Ragtag" to the "Bobtail," having been run constantly for the past ten months, there is every prohability that a water dividend, of 500,000 gallons to the share, will he declared towards the end of the year.

The working miners, as it was expscted they would do, have during the week commenced gravel washing on a number of hydraulic claims, the owners of which had been restrained from oparating the same hy injunctions issued hy the courts. As yet, these men have not heen molested, and many of them are of the opinion that no legal measures will he taken to estop them from going on with their work.

Besides a healthful progress in gold and silver mining, there is to he noted a good deal of activity in several other branches of the husiness, nearly all of which, though they have at one time or another heen greatly depressed, eome of them almost to the point of extinction, are now fairly prosperous. Thus, the prodnction of horax, lead, coal, eulphur, copper and quickeilver ie now remunerative, though there have been seasons when none of theee commoditiee could here he made or mined with profit. So, also, we have at last got to making iron in California with every prospect that the enterprise will prove a snccess. Nitre deposits of enpposed value have lately been found in Nevada and are about to he worked. Salt ie being, and for many years has heen, gethered in great quantitiee in that State. We are also mining antimony, manganese, mioa, end varions other metels and minerals in a emall way at different points on the coast.

Quite recently we heer of efforts heing made at reviving gold mining in the extensive region lying to the east of the Similkameen country, British Colnmbia. This is the work of the old campaigners who, rushing into and over that country eome 15 or 20 yeers ago, left it for the virgin mines of Ideho and Montana, well knowing that they had only skimmed the surface of these hastily ahandoned districts. Encouraged hy the rapid approech of two overland railroads into that region, these old-timere return, well knowing that they go hack to a good thing, these mines having eince they left heen hut little worked. Just now the old Kooteney district appeare to he the scene of the most importent mining operations in that quarter.

California Mines and their Occupants.

In many respects mining in California is pursued under conditions widely different from those that exist in the other Statee and Territories west of the Rocky Mountains. Out of these differences, which are due to a variety of causes, there arise many advantages to those engaged in the husiness in this State. Among other noticeable features that distinguish the California mines is the great linear extent of her principal gold field, which, striking along the lower slopes and ontlying foothille of the Sierra Nevada and trending on the north, westerly into the Coast Range, extends with hut little interruption through more than eight degress of latitude.

Beginning near the southern boundary of the State, this auriferoue helt, hearing N. N. W., reachee clear to and heyond her northern border. Nowhere else, perhape, is there to he found a metalliferons zone of such great length so little interrupted hy barren spaces, the latter amounting to hardly more than 10% of the whole. Tbis zone varies from 20 to 60 miles in width, its average width heing about 40 miles. The climatic variatione along it depend more on elevation than latitude. As its westerly, lower half attaine hut a moderate hight above the sea, it is characterized by warm summers and nearly snowlese wintere. Along its easterly margin, which everywhere reaches a considerable altitude, and at some points extends quite to the summit of the Sierra, the snow falls to a great depth in winter. Still, the degree of cold here is not excssive; few of the larger lakes and streams ever freez ing over even in the coldest winters. To obtain ice of a desirable thickness for storage is alwaye a difficult matter. This gold-hearing helt ie everywhere well watered and timhered, large creeks and rivers crossing it at short intervals, and eplendid forests of oak, pine, spruce end cedar covering nearly the whole of it.

In a sanitary point of view the climate is nnrivaled, there heing nowhere in the world a more healthful region or one hetter fitted for the hahitation of civilized man than this coastwise-lying conntry and these foothill lande of the Sierra Nevada.

Another peculiarity of onr minee rests in the fact that the gold here occure under conditione so varied as to widely diversify the methods and appliances employed for searching after and procuring it. Out of thie feature of our auriferous deposits have grown the multiplied forms of mining here in use, snch as the hydraulic, tbe drift, the wing-dam and other novel modes of gold gathering peculiar to California. Then, hesidee onr gravel hanks, river heds and pliocene channels, we have our seam diggings, gold bluffs and beaches, all a clase of deposits rare in other conntries, some of them having elsewhere never heen met with. Of course, none need hs told that we practice here vein mining on an extensive scale, auriferous quartz lodes occurring in great numher throughout all parts of our gold fields.

With mineral resonrces so diverse in kind and so widely disseminated, the husiness of gold mining gives here employment to a numerous ponulation, the most of whom work for themselves on their own claims, upon or near which they permanently reside; for it is to he remembered that the present occupants of the California mines are not now the restless, nomadic crowd they once were, ready to pnll np stakes and stampede for the site of any rumored hig find, however distant or difficult of approach. On the contrary, the denizens of our minee are, at this day, rather noted for their stahle hahits and stay-at-home proclivites, a disposition that has grown strong npon many of them of late yeare.

This comee of the fact that multitudes of these men, excited hy the rumors of rich mineral discoveries made afar off, having in times past, egain and again gone away in searoh of the seme to their great disappointment and detriment, have at last determinsd to remain in their old haunts working the mines there for what they are worth.

In considering the growing indieposition on the part of our miners to roam ahout, there is also that element which conoists of the young men horn in the minee to he taken into the account, and who having their homee and attachmente there, cannot easily he lured away.

Moreover, it ie the case that very few of these yonth are heing oonsumed by that spirit of enterprise that prompts ambitious young men to tie up their worldly effecte in a cotton handkerchief and seek fame and fortune ahroad. The numher of these who will reach the Presidency by way of the tow-peth will probably he small.

Nevertheless, it etende to reeson that the most of these yonng people will have to go to work at something or another, and as there is not much else for them to do, they will neceesarily have to engage in mining; and they will have to do this where they are, for, while some of the far out-lying countriee may open a hetter field for the experienced and hardy prospector, these would, as a general rnle, prove hut a poor place for the California born boy who, reared in a genial climate, enjoying every comfort and many luxuries, would find it hard indeed to adept himself to the coerse fere and thorough life incident to the pioneer mining camp. Wherefore, hetter it is he remein amongh is friends and there live and lahor near the epot of his hirth. We could wish his capecity for doing reel hard work were hetter than it ie, for it ie in thie perhaps, rather then in an unwillingness to work that the California hornhoy is deficient. Spirited and tolerably well developed of limh he may he, hut that he lecks stamina—the ability to perform severe mannal lahor, there is no denying.

But, for all this, he will have to make the effort—he will, in fect, have to actuelly perform a good deal of downright hard work, getting through with it in some sort of way at least. And hy heginning right he will, we fancy, get through with it pretty well. Let him commence moderately, doing light work and ehort hours till he gets inured to the business. In this way it is surprising how eoon even a slender, dclicnte youth, lahoring in the fresh air and the sunshine, with regular hours, steady hahits and wholesome diet, developee into a strong, vigorous man and good worker. If the industrial neophyte at times hecome a little tired, or even pretty badly nsed up, this ie not always an unmitigated evil.

Mucb etrenuous effort, some self denial, a little hardship, not to say absolute suffering, does not always hurt us humans. We are here to strive and endure, not lead lives of sensual indulgence and unquelified ease. This passive sort of existence may do for tbe hivalve hut not for man, whose appetites will make him captive if not restrained by reason, and whose faculties will decay and die if not duly exercised in every healthful direction. The happiness that comes of mere inaction is the enjoyment of the clam at high water. Dend matter is quiet enough. The lifeless tree, the stone, the extinct volcano, have no troubles. Man, belonging to the highest order of intelligence, has the most of these. And since this is so, he ehould accept them as being necessary for his welfare and turn them to such account as they seem designed to eerve in the economy of creation. It was not decreed that man should eat his hread hy the eweat of hie hrow nntil it was found that the plan for providing him with everything he required, without effort on his part, was a failnre.

Let not our young friends in the mountains, then, he led away by the heresy that useful, hard work is a thing to he deprecated and avoided. On the contrary, let them hail it as a great good, the practice of which will secure to them health, happiness nnd independence. They live in the hest land on which the eun shines. California is pre-eminently the poor man's country. In no other can the moneyless multitude so readily employ themselves, find employment or make shift, if so incliaed, to get along without any employment at all.

But this latter is an expedient to which, we opine, few of our mountain horn boye will feel disposed to have reconrse, for it must he admitted that, whatever their other faults and deficiences, they are not lacking in a certain epirit of manlinese and independence. They are not what may he termed worthless, certainly not vicious. The typical hoodlum of the larger towns is not much seen in these mining communities.

Still, all too many of these youths are verging toward a stage of incipieut loaferdom, and unless set to work earning an honest living, will become so confirmed in their idle and shiftlese habits, that they will he unable ever to do so. Already a large percentage of them are what in the language of the southwest may he termed "ordinary, no-account, trifling sort of persons;" which condition, if suffered to become chronic, will incapacitate them from ever becoming usefnl or self-snstaining members of society.

Recurring to the remarks with which we set ont, touching our hroad mineral domain with its varied deposite and the advantages to the miner growing out of the eame, let it he remembered hy the on-coming generation, that this great heritage is theire if only they poesess enough indnstry and enterprise to turn its resonrces to practical aoconnt.

PERSONAL.—Mr. C. G. Yale, editor of the MINING AND SCIENTIFIC PRESS, sailed on Monday for San Diego to obtain a brief ohange of air and scene which long and close attention to his work hes rendered necessary. We trust the trip may replenish his strength and give him the freshness of thonght which followe a pleasant respite from conetant application.

THE honee of Washington Butcher'e eone, wholesale provieion dealers hae just failed for $1,000,000 after heing in husineee in Philadelphia for 121 years.

The Hydraulic System of Draining Mines.

(CONTINUED FROM PAGE 249.)

pressnre hy means of plnnger pumpe, *T*, whicb in tnrn are operated hy a compound eteam engine, *O*. These pumps, which supply the accumnlator with water and kcep it at a pressnre great enough to run the two nndergronnd pumps, *P*, take their suction from the reservoir, *N*, into which the retnrn water is discharged.

Now, since this pipe which snpplies the pnmps, *P*, is of such greet length, and moreover, since the whole mass within it must he put in motion and brought to rest again during each stroke of the pumps, *P*, it is evident thet eome mechanical contrivance must be introduced for the purpose of lessening the jar in the pipes ceused hy the sudden stoppage of such an imnense mass of water. The arrangement hy which this end is accomplished, will be reedily nnderstood hy referring to the drewings. It is constrncted as follows: Let *E* (in general plan) he the velve which shuts off supply water from *P*. Close to the underground pumps there are firmly fixed two cast-iron cylinders, *C* and *C*, in which the plnngers, *L*, *M*, cerrying the crosshead, *D D*, ere free to move. On either side of the arm, *D D*, are etrong eprings, *S*, *S*, held in position hy the abutments, *B*, *B*. Now, when water in enpply nnd return pipes is at rest, the arm, *D D*, is exactly in the middle hetween the cylindere, *C* and *C* (since the plungers, *L* and *M*, are eo proportioned that the total pressure on *L* is precisely equal to total pressure on plunger, *M*). But after the underground pump, *P*, has completed its etroke, and the total mass of water in the eupply pipe has to he brought from a velocity = *v* to a velocity equal to zero, the inertia of thie mess (due to velocity *v*) is supposed to he gradually reduced to zero hy the plunger, *L*, *M*, heing forced (on account of extra pressure on *L*) over to the right side. The distance it travels to tho right depends, of course, upon the extra pressure produced by checking the velocity of supply water, and also upon the strength of the springs, *S*, which hegin to he compressed as soon as *L* *M* begins to move. Now, after the crosshead has heen forced over by thie extra pressure to its maximum extent (the water in the three columns also coming to rest at this moment), the compressed springs, *S*, will immediately react to place the crosshead and plungers in their central position, ready to agnin take up the inertia of the mess in supply column on the return stroke of the pumps.

Thus, the object of these springs, *S*, *S*, is not only to assist the water in the return column in taking up the inertia of the water in the supply column, hnt chiefly to replace the plnngers, *L*, *M*, in their central positiou after the masses in the three columns have come to rest.

The general arrangement of tbe eystem having heen described, an account will now be given of the manner in which the work is performed hy the pumps, *P*. In the drawing I have ehown in detail that portion of the nnderground pumps lying hetween the lines, *B* and *B*, on the general plan, leaving out, of course, that portion already explained for taking up the inertia of the supply water.

There are two of these underground pnmps, sitnated on the 2400 level of the mine, hut eince they are similar and work independently of each other, it is necessary to describe hut one of them. They hoth take their eupply water through the valve, *E*. Acting indepsndently as they do, they will not necessarily commence nnd finish their strokes at the same time. But, in order to discuss the eystem under its extreme condltions, I will consider the two pumps as working together, thereby making the velocity of the snpply water and the inertia of the moving masses a maximum.

Therefore, in each pnmp, let *O*, *O*, and *O.*, *O.*, see detail drawing, he the four pressure cylinders, and *T* and *T.*, the pump cylinders for raising the drain water to the Sutro tunnel. Let *V* and *V.* be the valves leading to the pressure cylinders from the supply and return pipes, and let the plungers he connected with a croeshead (es ehown in drawing), so that when any movement of the plunger, *O O.*, takes place, the plunger, *T T.*, will he cerried along also.

Now, let ue follow the operation of tbese pumps, first assuming, however, that the pressure of the water in the eupply pipe is great enough to prodnce motion of the plungers, *O*, *O*.

First, euppose the valves, *V*, to he opened (valves, *V.*, remaining closed). The two plungers, *O O.*, will he forced over to the right, carrying with them the lnrger plunger, *T T*. While *T* travels to the right, the space left hy it is immediately filled with drain water coming through the euction pipe, *W*. Now, suppose valves, *V*, to he closed and the stroke finished, the valves, *V.*, are then opened, and the pressure of the snpply water against the plnngers, *O.*, forces them to the left, and the water remaining in cylindere, *O*, ie forced through the valves, *V*, into the return pipe, and thence into reservoir, *N*, upon the surface. At the eame time, the water which was drawn into cylinder, *T*, on preceding stroke, is now forced (on acconnt of check valve, *C*, closing) through *D.*, into discharge column, *D*, and thence 800 ft. into the Satro tunnel. Again, while this stroke to the left is heing made, the space left hy plunger, *T.*, is heing filled with drain water through euction pipe, *W.*. At the completion of this etroke, valves, *V.*, nre closed and valves, *V*, are opened, the crosshead and plungers again move to the right, and the water remaining in the cylindere, *O.*, ie again forced through return

column into reservoir, *N*. At the same time, the water in cylinder, *T*., is forced upward (on account of check valve, *C*., being closed) through *D*., into *D*, and thence to Sutro tunnel. When crosshead and plungers are again over to the extreme right, valves, *V*, are closed and valves, *V*., opened, and thus the operation continues, the valves, *V* and *V*., being worked automatically by means of tappets carried by the crosshead. The number of strokes made by these pumps evidently depends upon the pressure of water in the supply pipe, and also upon the rapidity with which the valves, *V* and *V*., are opened and closed.

In the preceding, I have followed the action of but one underground pump, but, as I have said before, the two are alike in every respect, and both draw their water from, and discharge it into the same columns.

From the above remarks, it will be seen that the sole object of these two underground pumps is to raise the drain water from the 2400 level of the mine to the Sutro tunnel, a distance of 800 ft. The object of the accumulator, *A*, upon the surface, is to accumulate the water within it, under a pressure great enough to work the pumps, *P*, and the object of the compound steam engine and pumps, *T* (on the surface), is to supply the accumulator with exactly the same amount of water taken from it, to run underground pumps. Furthermore, it will be noticed that the same amount of water which is used to run these pumps, *P*, is returned to reservoir on the surface, from whence it is forced into the accumulator by pumps, *T*, to be used over and over again.

Right here it might be well to mention the fact, that the surface pumps, *T*, have been constructed with a capacity great enough for two more pumping engines, similar to those just described (*P*), so that when a depth of 1,000 ft. more is reached, this extra set of pumps will be put in at the 3400 level, and the process will go on as before. In the event of this new set being started, the velocities in the different columns, as well as the inertias of the masses, will be increased.

A Convenient Apparatus.

(Written for the Press by C. H. Aaron.)

A very convenient arrangement for continuous filtration of a liquid, or for washing a precipitate on a filter, is represented by the accompanying skeleton diagram.

Upon a table, *A*, stands a vessel, *B*, containing the liquid, which latter is conveyed to the filter, *C*, by the rubber tube, *D*. The funnel containing the filter rests in a hole in the tilting shelf, *E*, beneath the table. Upon the tilting shelf at *F* is a counterpoise, which is made stationary on the shelf when the arrangement is used for filtering a liquid. The counterpoise is then so adjusted as to balance the funnel when nearly full of liquid. If the liquid should pass into the funnel too quickly, so as to be in danger of running over, its weight overcomes that of the counterpoise and the shelf tilts, drawing downward the wire stirrup, *G*, which passes over the rubber tube, *D*. The tube is thus compressed, and the flow of liquid checked or stopped, until the funnel has become so lightened that the counterpoise preponderates, when the shelf tilts the other way, the stirrup is raised, and the flow of liquid is resumed.

In practice the machine soon adjusts itself so as to keep the liquid in the funnel at a uniform hight.

When the apparatus is used for washing a precipitate, or for leaching a sample of ore, etc., it is desirable that a certain quantity of the liquid should be allowed to accumulate in the funnel, and that the supply should then be cut off until that has all run out, when a fresh quantity may be allowed to flow in.

To effect this, the stationary counterpoise at *F*, is replaced by a ball, which rolls freely in a small oblong box placed on the tilting shelf. The length of the box is such that when the ball is at the end nearest to the fulcrum of the shelf, its weight is just sufficient to raise the funnel with the substance to be washed, and thus to open the supply pipe. At the same time, in consequence of the tilting of the shelf, the ball rolls to the other end of the box, and in this position has a sufficiently increased leverage to enable it to counterpoise the funnel until the latter is nearly full of liquid; the weight of the liquid then causes the funnel to descend and close the pipe; the ball again changes its position, and the funnel remains down until it is drained, when it again rises for a new supply of liquid.

The interior length of the box in which the ball moves, is easily adjusted by means of inserted blocks of wood, by which means also the ball may be converted into a stationary counterpoise, when so required for filtering purposes.

As used for filtering, this apparatus is described in the *Chemical News*, 1868. The modification by means of a moving counterpoise is my own, and replaces a much less simple affair described in the *News*, in which two tilting shelves, two stirrups, two funnels, and a syphon within the upper funnel, are used.

Too Busy.—It is spoken of as a fact, without precedent in the history of American industries, that large numbers of exhibitors at previous local industrial exhibitions, have been too much pressed with orders during the past season to permit them to produce specimens of their handiwork at the public exhibitions which have been held this fall.

Application of Standard Measures to Industrial Processes.

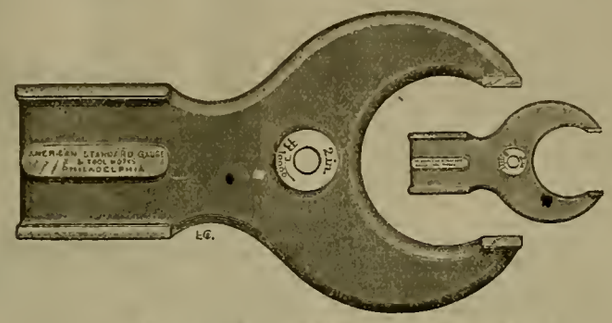
The following valuable and interesting paper was read recently before the California Academy of Sciences by John Richards, Superintendent of the San Francisco Tool company, and we publish it by his permission:

The subject of invariable Standards for dimensions and weight, with the apparatus for determining and comparing, is one of great practical importance, entering as it does into all kinds of industry and commercial transactions.

It has also to do with scientific research, and is fast assuming an international importance, as intercourse widens and exchanges extend.

But little attention of a popular kind has been given to exact Standards. The matter is generally regarded as a scientific abstraction, and I am well aware of the difficulty to be encountered in attempting to treat the subject in a public lecture.

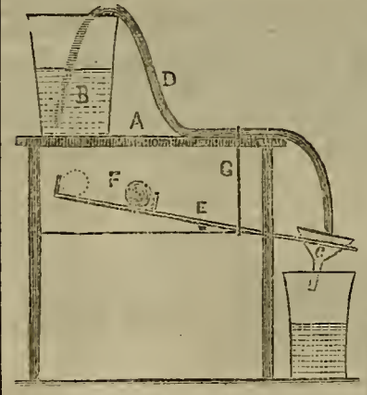
This difficulty will be lessened, no doubt, if at the outset it is considered how far these exact Standards have to do with practical affairs. Common rules, yard sticks with all



CALIPER GAUGES REFERRED TO IN THE PAPER.

lineal measures, so also weights (in common use) and cubic measures, are but derivatives or copies from some Standard; some fountain head, so to speak, which must be resorted to in cases of doubt or dispute.

Every mechanical operation, as well as every commercial transaction, necessarily deals with some Standard—some measure of quantity—either of material or values. The latter is expressed in coin, and this again is defined by exact weight, so that we are continually, in every



Device for Filtering Liquids.

kind of business, dealing with Standards of some sort.

Such Standards have been during the present century adopted by most civilized nations, usually under the supervision of a few scientific men and mechanicians, who are not always anxious to make their work a matter of popular knowledge. The late Mr. Saxton for example, who, while in charge of the Standard Department, at Washington, invented and constructed apparatus, that under most other circumstances would have rendered him famous, yet not one person in a hundred has ever heard of him.

For these and some other reasons it is thought that a brief lecture on the subject of Standards will have some interest, and in order to inspire confidence in what is said, it will be proper for me to remark that I spent many years in connection with the matter, and founded the first commercial manufacture of gauging implements in this country, and constructed or had constructed the first measuring machine adjusted accurately to the Imperial yard, and the U. S. Standard, at Washington, I mean a machine for mechanical purposes.

My lecture will be divided into three parts, the first relating to the economic value of Standards and their practical application; second, to the derivation of Standards now in use, and thirdly, to some implements and mechanism for determining and transmitting dimensions.

In respect to Standards for weight not much need be said, these are derived from Lineal measure, so also is Dry and Liquid measures.

It is easy to understand that when a lineal or length Standard is once assumed, it is not difficult to measure a specific quantity of some material, water for example, and call it a pound or a gallon. The gravity of distilled water is quite the same in all parts of the world, temperature being taken into account. If the gallon or pound were lost they could soon be restored with great precision by means of an uniform lineal Standard, if such a one existed.

Lineal or length Standards are, therefore, the basis of all, and to these mainly attention will be called this evening. In a consecutive treatment of the subject the derivation of National Standards should come first, but, as the whole subject may be new to some present, and part of it to all, the object of the lecture, it is thought, will be best served by first treating of the economic value of Standards and implements for exact measurement.

The usual limit of accuracy in implements employed in common machine fitting is one ten-thousandth of an inch. English makers claim more for gauges made in that country, but my own experiments have led me to believe this limit close enough. In this country there are three grades of precision employed, one five-thousandth, one ten-thousandth and one twenty-thousandth of an inch. The implements present correspond to these grades. The test rods covered with wood are within a limit of one twenty-thousandth of an inch at 70° of temperature. This, to many, or, indeed, almost every one, will seem a needless refinement but it is not so. So far from it, that there is every day fitting done in the machine shops of this city that comes within a limit of one ten-thousandth of an inch—not measured and determined by implements, but by trial fitting.

In common fitting, even on the coarser kinds of work, one-thousandth of an inch will spoil a fit. The difference, one ten-thousandth of an inch, will cause a steel pin to fit firmly in a hole or permit it to drop out loose.

In making gauging implements, such as you see here, the one ten-thousandth of an inch becomes a tangible quantity, and is dealt with the same as eighths or thirty-seconds of an inch.

In making such implements, the work, after trial, is always marked with chalk, 1, 2, 3, and so on, these figures meaning one ten-thousandth of an inch. The workmen deal with these sizes with the same confidence and facility they would with one one-hundredth of an inch in the coarser kinds of work.

Watches, firearms, sewing machines and other articles of the kind, are made with dimensions that come within a one ten-thousandth limit, not on all parts, but in moving joints when duplicated parts are employed.

Sight, unaided by glasses, fails long before such limits are reached, but touch does not. A workman will, and does, continually set calipers to one ten-thousandth, and there is no one present who would not at once detect a difference much less than that between the implements of the kind I hold in my hand.

When the ordinary mechanical processes in metal fitting involve such exactness, it is easy to understand the importance of precision in National Standards or in the fine class of implements such as are used for reference.

I am at much loss to present this subject of exact dimensions in such a light as its practical importance demands, and I must claim a little on behalf of your imagination. The subject is technical, yet I think can be grasped even by those who have not previously given attention to the matter.

Modern manufactures may be said to rest upon the division of labor. This term is employed to describe that state of things where one person learns a particular trade or calling in distinction to a barbarous state, where each person attempts to supply all his wants by his own efforts.

The principle reaches back to the very beginning of civilization, and is indeed the measure of what we may call industrial civilization and progress.

In a barbarous state there is no division of labor; there are no carpenters, farmers or tailors. Each person attempts to construct his own hut, procure his own food and raiment; but production in the usual sense of that term, cannot begin until there is a division of labor and people follow special callings.

Further on these callings are subdivided into branches, and the subdivision of labor goes on until the highest skill may be concentrated in some small thing, the tempering of steel, for example, or the production of minute screws or parts of machines.

Keeping in view this first proposition that our skilled manufactures rest upon a division of labor, I now add a second one, which will bring us nearer to standard sizes, namely: That, in most of our manufactures, the division of labor depends upon a duplication of parts, making two or more things precisely alike.

In this country, about 20 years ago, we were able to begin the manufacture of watches, employing the dearest labor in the world in competition with the cheapest of Europe, that could be called skilled. The difference between Boston and Geneva was more than as three to one in favor of the latter.

The reason generally given for this bold venture and its success is that "machinery was employed," and that reason was correct in so far as the modes of operating, but behind the machinery and qualifying nearly all advantages that could be gained by it, was the more important matter of duplication, making the parts of watches uniform and interchangeable. That was the main secret, the "principle," so to call it, on which the whole matter rested.

Machinery produces duplicates, hand labor can not, and because duplication was possible the division of labor could be made complete. To this principle of duplication we can ascribe our success in many manufactures, and perhaps the whole success we have had in competing with Europe in the finer kinds of metal work. Standards and gauging implements permit a duplication of parts, and this brings us to the connection with industry.

All who have read Adam Smith's "Wealth of Nations" will remember his description of pin making—how a man who cut off the wire, formed the points, made the heads and put them on could make only a few dozen pins in a day, but, in a factory, where different persons cut the wire, pointed it, made the heads and riveted them on the product was increased twenty fold. This was nearly 100 years ago. The division of labor has gone on, the duplication of parts succeeded, and now the cost of making a thousand pins is no more than it was to make a score when the "Wealth of Nations" was written.

It is evident that if the parts of any article are to be made by different persons such parts must be made to some common gauge or standard so they will fit together, otherwise each person would have to himself complete an article, fitting together by trial the different parts, and he would be wholly unable to make two articles precisely alike. Nearly all kinds of work are done by some Standard that permits duplication. A carpenter may make a table and have all of its component parts ready to be joined together without trying or comparing any of them, or several workmen might make different parts of the same table with the assurance that all would fit together. To do this there would be employed a scale of lineal measure, called a rule. The dimensions of the parts would correspond to feet and inches, or, as we might say, to our National Standard of length.

In constructing works of metal, the same thing applies, with the difference that the material is hard and inelastic, and dimensions must be much more accurately dealt with.

As before remarked, sight fails long before the required precision is attained, and the sense of touch is resorted to. This applies to all parts that are closely fitted, and by the use of standard gauges or corresponding gauges, the different parts of a machine could be made in London, Philadelphia and San Francisco, and fit together the same as if prepared at one place.

The custom is to prepare drawings of the different parts of machinery, and mark on all the proper dimensions. Such dimensions are or ought to be from our National Standard, and if so, the parts can be made at different places and by different persons. Any number of workmen can, in this manner, be engaged on a particular work.

In all large works in the Eastern States, also in nearly all parts of Europe, the parts of machinery are made to Standard dimensions. In Great Britain and a few of the northern European countries to feet and inches, but in the south of Europe and most continental countries to the Metrical Standard.

The value of machinery, or similar work, is unquestionably affected by the fact of its being so fitted. I am not aware of how much effect this would have, but do know that specifications for machine work commonly specify Standard dimensions, and when not specified, contracts are understood to call for that as an obvious condition.

No one fully aware of the true importance of the matter would care to purchase machinery or other work made to special dimensions or irregular dimensions. No part could be replaced except by trial fitting, and repairing would be very expensive.

[To be Continued.]

Uncalled for Money.—About $10,000,000 are now lying idle in the U. S. Treasury at Washington for the redemption of matured bonds on which interest ceased at various dates from before Jan 1, 1867, to July 1, 1881. There is also an amount of some $12,000,000 or more of United States fractional currency not yet presented for redemption. The probability is that but little, if any, of this large amount will ever be called for. It will eventually go to the benefit of the Government. The great bulk of the paper evidences of this indebtedness, has most probably been either lost at sea or burned up on land. No inconsiderable quantity of the last amount is held by individuals as a curiosity and memento of other days—it being worth more for such purpose than for its face value in coin.

The Public Lands.

We stand a fair chance now to get some authoritative information concerning the whereabouts of public land still available to entry, and to have it surveyed, mapped, etc., so that the selector need not work to so great disadvantage in the tiresome hunting which he has had heretofore to practice. The surveying, etc., of our government lands is to be urged upon Congress at the coming session and the appropriation of money to secure the work is to be asked for. The present movement to secure this is being undertaken under the auspices of the Board of Trade of this city, which seems to be awakening to the need of doing something to induce desirable immigration, and is holding meetings for the discussion of the best means of securing it. As a preliminary step toward rendering our public lands more available, a communication was addressed to Theodore Wagner, U. S. Surveyor-General for California, and a reply was received which embodied the following statements:

The area of the State of California, as estimated by this office, is 100,500,000 acres. The area of surveyed agricultural and mineral land is 58,828,207 acres, and of unsurveyed agricultural and mineral land 29,237,000 acres, making the aggregate area of the public lands 80,065,267 acres, leaving an area of 12,434,733 acres, divided as follows:

	Acres.
Private or Mexican grants	3,758,151
Indian and military reservations	318,631
Swamp and overflowed lands	1,720,751
Lakes, bays, navigable rivers, salt marsh and tide lands	1,637,200
Total	12,434,733

The surveyed lands embrace all the large plains and main valleys of the State, as well as the greater portion of the high table lands in the Sierra adapted for the grazing of large herds of cattle and sheep. They also embrace a large portion of the two timbered mountain regions—the Redwood belt, extending from the Bay of Monterey northwesterly to the Oregon line, for a distance of about 350 miles, and from the sea coast easterly toward the Coast Range mountains, with a general width of 30 miles, and the other covering with valuable timber of pine, fir and spruce the slopes of the Sierra Nevada, between Mt. Shasta on the north, and the junction of the Sierra Nevada with the Coast range on the south, for a distance of about 500 miles in length, with an average width of 50 miles. Both of these mountain regions, as well as the other surveyed portions of the Coast range running southeasterly from the Bay of Monterey to the south boundary of the State, are sufficiently watered, and contain many small fertile valleys and sunny and grassy hillsides and oak openings, well adapted for the raising of all kinds of California fruits and vegetables and offering cheap and comfortable homes for industrious farmers.

The unsurveyed lands chiefly embrace portions of Del Norte, Siskiyou, Humboldt, Trinity and Shasta counties in the northwestern; of Modoc, Lassen and Plumas counties in the northeastern; of Placer, El Dorado, Alpine, Tuolumne, Mariposa, Fresno, Tulare and Kern counties in the central; and of Mono, Inyo and San Bernardino counties in the eastern part of the State; also of Santa Clara, Stanislaus, San Benito, Monterey, San Luis Obispo, Santa Barbara, Ventura, Los Angeles and San Diego counties on both slopes of the Coast range of mountains.

The unsurveyed lands, although in the main rough and mountainous, contain many fine spots for homesteads, treasures in water power for mill sites, in valuable timber and in precious metals, the development of which would furnish homes and occupation for a large population. For this reason these lands should be speedily subdivided. I cannot, however, tell when it will be done, as it depends altogether upon the yearly appropriations made by Congress for the surveying service.

It is quite true, as has been often stated, that the best portions of the public domain have passed into private ownership under the different ways of taking up land which have been provided by law; but there are, no doubt, tracts of comparatively small area still available, and should be turned to agricultural account. The Board of Trade is endeavoring to obtain from the local land officers through the State, general statements of the land still open in their several districts. The first report received is from J. C. Bradley, Register at the Marysville office, and it is as follows:

There are nearly 1,200,000 acres surveyed and unsurveyed government lands in this district not yet disposed of. These unsold lands are all or nearly all, foothill and mountain land, and a greater part thereof so mountainous and broken as to render them unfit for cultivation or settlement. They are not confined to any particular locality, but are scattered all around, each county in the district containing more or less. There is no place or locality containing any quantity of unsold land suitable for settlement that I could at present call your attention to, the valley lands having all been disposed of some time ago. It is true that there are large quantities of foothill land in the counties of Nevada, Yuba and Butte, now considered almost valueless, which, in course of time, may become valuable for orchard and vineyard purposes, but until cheap means for irrigating these lands can be devised and carried into effect, it will be useless to send immigrants thither with the expectation of being able to make a living and build up homes for themselves and families. In the southwestern portion of Plumas county, not far distant from the town of Quincy, lies the largest body of unsold land now in this district, and it is possible that this section of country could absorb a larger population than there is now, but the altitude is so great, and the winters consequently so long, that farming or stock raising cannot be made as profitable as in places nearer the valley. There is a range of mountain and foothill land running up through the eastern portions of Napa and Lake counties and the western parts of Yolo, Colusa and Tehama counties, some of which is yet unsurveyed, where I think the attention of parties desiring to make new homes might be directed. In this mountain range no one need expect to find any large amount of arable land; but there are many little valleys scattered among the mountains where parties wishing to go into the stock-raising business might profitably locate.

The Marysville district is one which has been prominently before the public since the early days, and has been run over by hosts of miners and locators. It is natural to expect that less land would be left in such a region than in some of the newer districts, and this the reports, which may be expected from the Registers therein, will show. We shall give our readers all information on this subject which can be obtained, for aside from the openings for immigrants there are many of our own people who would like to get more room for their orchard and vineyard enterprises; and they are prepared to turn good land to quick account whenever they get a hint of where it may be found.

END SPLITTING.—Logs and planks split at the ends because the exposed surface dries faster than the inside. Saturate muriatic acid with lime, and apply to the ends like whitewash. The chloride of calcium formed, attracts moisture from the air and prevents the splitting.

"THE $1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in Use in the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Utah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

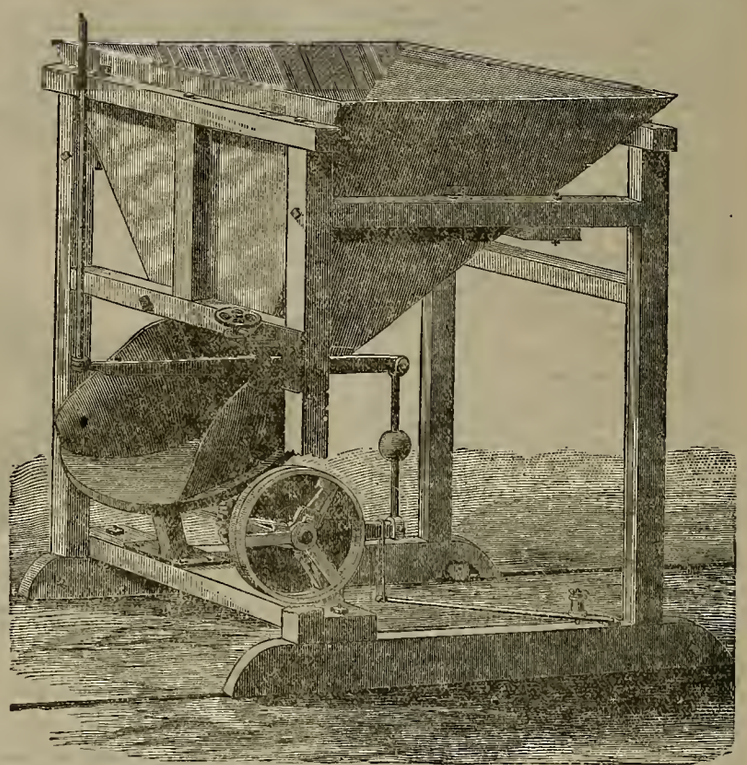
The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King," Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sola" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.



JOSHUA HENDY, Agent,

Machine Works, 49 and 51 Fremont Street, San Francisco.

Manufacturer of Quartz, Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRAHAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING from the Akron Iron Company, of Akron, Ohio.

Dealer in New and Second Hand Engines, Boilers, and all Descriptions of Machinery.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

NOTICE.

The office of the STETEFELDT FURNACE CO., having been removed to New York, parties wishing to obtain information in San Francisco about the Stetefeldt Furnace will apply to Messrs. Prescott, Soott & Co., Union Iron Works San Francisco. C. A. STETEFELDT.

SHEET IRON PIPE.

FRANCIS SMITH & CO.,
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteslan Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

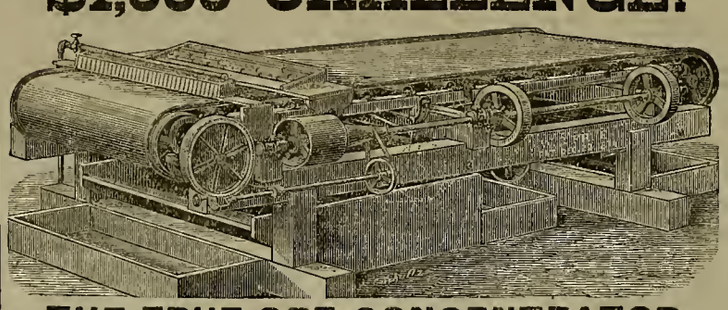
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also

SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.

☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.
Nos. ONE, TWO and THREE.
Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞Triple Force Caps and all Grades of Fuse.

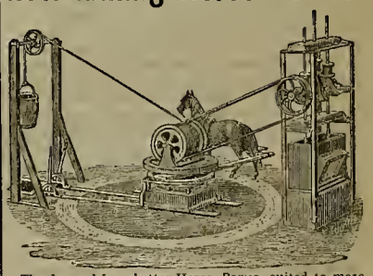
New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.

This power is light and strong, so that two or more horses can be used for crushing ore or other work.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING SEPTEMBER 27, 1881.

247,479.—REMEDY FOR CURE OF SCAB IN SHEEP—Brittain, Rolley & McGeorge, Springville, Cal.

247,535.—AMALGAMATOR—N. D. Burlingham, Garden Valley, Cal.

247,545.—MUDRINO FOR BOILAR FURNACES—P. F. Dundon, S. F.

247,546.—FURNACE FOR STEAM BOILERS—P. F. Dundon, S. F.

247,663.—FAUCET—T. J. Loftus, Sacramento, Cal.

247,571.—RAILWAY BALLOON, ELECTRIC TRAMWAY AND TRUCK—C. F. McGlashan Santa Barbara, Cal.

9 885 (Reissue).—DAVICE FOR RAISING TAILINGS FROM MINES—W. A. Rogers, Folsom, Cal.

247,535.—GRINDING AND PULVARIZING APPARATUS—W. C. Stiles, Nevada City, Cal.

247,705.—STUMP EXTRACTOR—W. A. Stoddard, Dallas, Oregon.

247,709.—BUCKLE—Sweyea & Lowe, Walla Walla, W. T.

247,720.—HAIR TONIC—Caroline Weisser, Los Angeles, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CENTRIFUGAL ORE CRUSHER AND PULVERIZER. Wm. L. Dawson, San Francisco, assignor of one-half to Isaac Stead. Patented Oct. 4, 1881. No. 247,749. This devise relates to certain improvements in that class of crushers or pulverizers in which a series of beaters is secured to a central revolving shaft, and inclosed within a stationary case provided with an opening or hopper into which the ore or other material to be pulverized is fed, so that it will be crushed by the rapidly revolving beaters and allowed to escape through suitable screens. An axle or central shaft is journaled upon the stand and revolved in an appropriate manner. Fitting around and attached to the central shaft is a drum, which has its body made of wood, the sides being protected by sheet iron plates, and the circumference provided with an iron band shrunk in so as to fit tightly. Beaters are fastened, and because of their rapid revolution there is immense centrifugal force generated which would tend to force them from their fastenings. The beaters are let through the iron band and driven into the drum in slots made for their reception. The shoes are so constructed that when they become worn they may be adjusted. About the central shaft and drum is formed casing in whatever sections may be found convenient to have access to the drum and beaters. The casing has two sides supported by the frame side and secured together by bracing rods. On the inside of the sides near the outer edges, grooves are formed in which transverse bars are placed, having their ends provided with a notch, in which is placed a small block. On these blocks placed in the notches of one bar, rests the next bar, flat side down, thus having openings between the bars, and when continued all around they form a circular screen within the outer casing and surrounding the drum, and within which the beaters revolve, crushing the ore and allowing it to pass off through the screen thus formed.

ROTARY CYLINDER FURNACE.—Geo. W. White, S. F. Patented Oct. 4, 1881. No. 248,000. The class of furnaces to which this invention relates, is that which consists of a hollow cylinder mounted upon suitable pulley-bearings in an inclined position; the fire-place or furnace being so placed that the heat and products of combustion are directed into and passed through the cylinder, while the ore is fed into its upper end, the rotation of the cylinder combined with certain projections on its interior causing the ore to travel toward its lower or discharge end, and at the same time the projections serving to alternately lift and drop the ore through the passing beat. The present improvements consist first of an arrangement for shifting the furnace to either inclination and feeding the ore in either direction; second, to the arrangement of parallel flues inside the cylinder around the main flue, which serve as connecting flues between the fire-place and chimney, and through which the heat and products of combustion are conveyed to the chimney, while the ore passes through the center or main flue and out of contact with the draft and products of combustion from the fire-place thus converting the furnace into a muffle, which adapts it for reducing that class of ores from which it is desired to expel metallic vapors and from which it is desired to exclude the products of combustion during the reducing process. By this construction the following advantages are gained: First, by tipping the furnace, ore may be fed through it, so as to pass, while being reduced, in the same direction that the heat passes, or in the opposite direction, as may be desired, and as may be best for the particular quality of ore being treated. Second, the fire and heat surrounds the main flue in which the ore is treated, and thereby furnishes a better heat with less fuel than can be obtained in rotary furnaces not so constructed. Third, the draft and products of combustion do not pass through the main flue or in contact with the ore.

LOCOMOTIVE.—John T. Davis, S. F. Patented Oct. 4, 1881. No. 247,802. This class of locomotives to which this invention relates is that in which the driving wheels act by rolling friction upon corresponding friction wheels secured to the same axles as the bearing wheels which run upon the track and which have a smaller diameter than said bearing wheels. It consists in a means for increasing the frictional contact between the drivers and the driven wheels, by means of hydraulic rams. The object being to acquire increased speed with less power, whereby economy of fuel and wear will result.

RAILWAY BALLOON AND ELECTRIC TRAMWAY AND TRUCK.—C. F. McGlashan, Santa Barbara. Dated Sept. 27, 1881. No. 247,571. This invention relates to a new tramway and truck, and, in connection therewith, it relates to certain modifications thereof, whereby results are produced which are all dependent upon the main invention. It consists in supporting wires, ropes, rods or rails above the ground by means of posts in such a manner that a peculiar truck may travel on said wire with safety. This traveling truck may be made to support a car and act as a running gear for it, or it may be utilized as a guide for a balloon. It may further be used as a means for connecting an electric circuit, whereby communication may be held with the car of a balloon or a moving train. The main feature is the tramway with its peculiar truck, but slight modifications are necessary in both to accomplish the desired results.

SMOKE CONSUMING FURNACE FOR STEAM BOILERS.—Patrick F. Dundon, S. F. Dated Sept. 27, 1881. No. 247,546. This is an improvement on the class of furnaces known as "smoke burners." It consists in the construction of a furnace having a bridge wall at its rear end, with the top so curved toward the furnace in combination with a blast of air or steam directed upon the surface of the fuel at an angle, so as to strike it near the bridge wall, whereby a counter-current will be induced, which will return the smoke, soot and unburned particles or gases toward the front of the furnace to be projected downward upon the incandescent fuel, where it is ignited and consumed before escaping over the bridge wall.

News in Brief.

THERE is danger of a water famine in New York City.

MICHAEL DAVITT, the imprisoned agitator, is soon to be released.

THE Mexican Government is about to colonize 200 Italian families.

A STATE Greenback camp-meeting is in progress at Jackson, Mich.

ANDREW NUNAN was killed by a fall in the Savage mine, Sunday.

THE Garfield fund has reached $339,898, and the Michigan fund $94,258.

REV. THOMAS HARRISON is striving to get up a revival in San Francisco.

AN Italian named Tanzi was shot by a night watchman at Sonora, Sunday last.

IN the Insane Asylum at Stockton, there are 786 male patients and 325 female.

A CIGAR factory employing 200 persons has been destroyed by fire in New York.

WASHOUTS are causing great trouble on the Atchison, Topeka and Santa Fe railroad.

DURING the past seven days 110 business failures have occurred throughout the country.

BANDON, Coos county, Oregon, people, make a good margin by selling their salmon at $10 a ton.

SOME large plate glass windows have been cracked in this city, by absorption of the sun's rays.

THE headquarters of the Russian Nihilists has been discovered, and 60 arrests have been made.

THE tobacco crop in the vicinity of Raleigh, N. C., is reported badly injured by the first frost.

CERTAIN Texas banks advertise to take all the Confederate bonds they can get at $2.50 per $1,000.

FEVER is epidemic in the Punjanb, Hindoostan, the deaths at Unnivisir averaging 200 to 300 daily.

AT Las Lunas, N. M., Friday night, three Mexican murderers were taken from jail by a mob and hanged.

IT is announced that it will require $1,000,000 to make good the losses caused by the Michigan forest fire.

A BOY named Floyd was thrown from a horse on the race track at Reno, Nev., and probably fatally injured.

BARON VON HAMERLE, Austro-Hungarian Minister of Foreign Affairs, died suddenly at Vienna, of heart disease.

THE overland stage from Oregon was robbed near Redding, Shasta county, Saturday night, by a solitary highwayman.

THE San Louis Rey *Star* suggests that a "quail cannery" be established there and the Eastern markets supplied.

A LATE severe frost has caused the Long Island farmers to hasten the gathering of their fall crops already badly injured.

The Mining and Scientific Press

Established May, 1860, this has long been the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, $4 a year in advance. Sample copies, 10 cts.

C. E. WETMORE—Alameda county.

A Compliment.

SANTA BARBARA, Oct 9, 1881.

MESSRS. DEWEY & CO., PATENT AGENTS.—Gents: Patent received. Many thanks for your promptness and accuracy. Whatever work I may have in the future, shall be yours. Very Respectfully,
C. F. MCGLASHAN.

Attend to This.

Our subscribers will find the date they have paid to printed on this label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F.D., at this office.

PARSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry O. Hanks, State Mineralogist.

ANNUAL STATISTICIAN of 1881.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 816 California st. Price, $4.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

—o—

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE O'HARRA CHLORIDIZING FURNACE.

Patented in 1878.

SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

—o—

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1 10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenual sulpburate of silver up to from 84% to 95% of the assay.

COMPOUND OXYGEN — NOT A DRUG

A NEW TREATMENT for Consumption, Asthma, Bronchitis, Catarrh, Dyspepsia, Headache, Debility, Neuralgia, Rheumatism, *and all Chronic and Nervous Disorders.*

ACTS DIRECTLY upon the great nervous and organic centres, and *cures by a natural process of revitalization.*

HAS EFFECTED REMARKABLE CURES, which are attracting wide attention.

HAS BEEN USED BY Rt. Rev. John J. Keane, Bishop of Richmond, Va., Hon. Wm. D. Kelley, T. S. Arthur, and others, who have been largely benefited, and to whom we refer *by permission.*

IS STRONGLY ENDORSED: "We have the most unequivocal testimony to its curative power from many persons of high character and intelligence."—*Lutheran Observer.* "The cures which have been obtained by this new treatment seem more like miracles than cases of natural healing."—*Arthur's Home Magazine.* "There is no doubt as to the genuineness and positive results of this treatment."—*Boston Journal of Commerce.*

THE OXYGEN HOME TREATMENT contains two months' supply, with inhaling apparatus and full directions for use.

SENT FREE: a Treatise on Compound Oxygen, giving the history of this new discovery and a large record of most remarkable cures. Write for it. Address

ADMINISTERED BY INHALATION. Drs. STARKEY & PALEN, 1109 and 1111 Girard St., Philadelphia, Pa.

Depository on Pacific Coast.

WE HAVE ESTABLISHED A DEPOSITORY OF OUR COMPOUND OXYGEN HOME TREATMENT at San Francisco, Cal. This will enable patients on the Pacific Coast to obtain it without the heavy express charges which accrue on packages sent from Eastern States.

All orders directed to H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., will be filled on the same terms on which we fill orders sent directly to our office in Philadelphia.

Patients ordering from our depository in San Francisco, should, at the same time, write to us, and give a statement of their case, in order that we may send such advice and direction in the use of the Treatment as their special disease may seem to require.

VOLUME XLIII Number 17

Ore Roasting Furnace.

We give on this page an engraving of a furnace for roasting and reducing ores, invented by J. H. Morton, of Keyport, Monmouth county, N. J. Referring to the drawing, *A* represents the masonry of what may be an ordinary reverberatory furnace, and A^1 the stack. At or near the top of the stack provision is made for allowing the introduction of finely crushed ore through a controlling valve, *D*, in a hopper, *E*. The stack has great breadth, and has a series of inclined reverberatory hearths as shown. The gases, after passing through the inclined hearths or passages, are conducted downward from the top of the stack, and after passing over a greater or less distance over a water surface, which will absorb the dust and a portion of the gases, they may rise again by their lightness, or aided by a fan. The down passage for the gases is indicated by *I*, and the water surface by *J*. The gases will ultimately be discharged through a flue, *P*.

To operate the device the attendant opens and closes the valves, C^1 C^2, etc., as he proves by practice is best, according to the class of ore under treatment. The current of air drawn into the stack by suction at any one of the valves, C^1 C^2, by the draft, strikes upon the upper face of the reverberatory hearth opposite the valve, whence it is deflected upward through the ore.

The hearths have upper and lower faces, *d*, *d*,' arranged in the form of a triangle to prevent the loss of heat by keeping the flame constantly in direct contact with the descending ore, and also to prevent the formation of eddies in the air current which would be formed where straight inclined projecting pieces are arranged in the stack.

The theory is to supply the ores in a comminuted condition adapted to be quickly acted on, and to cause the granulated or fine particles to roll and otherwise tumble along. The current of hot products of combustion containing sulphurous gases is met at the last turn of the flue by a fresh current of air, causing an immediate combustion of all the sulphurous vapors, thereby generating an intense heat.

Further effects of such air currents are to deflect the current of flame downward upon the floor of the opposite hearth, and to aid in the oxidation of the ores. In other words, after the ore has passed the controlling valve, *D*' and entered the series of reverberatory hearths it is subjected to a desulphurizing and oxidizing current of ascending flame. It is exposed to this current on a succession of highly heated inclined surfaces, and under conditions of agitation or tumbling which is claimed to be highly favorable to the complete burning of the sulphur and the oxidation of the metal. By effecting the desulphurization and the oxidation in combination with the reverberatory furnace, a^x, below, the invention economizes heat and reduces labor. No fuel is required on the hearths a^1 a^2, etc., only the gases which are relatively waste from the reverberatory furnace, a^x. The high temperature attained by the ore in the process of roasting is not diffused and lost, but is made a preparatory heating—to be immediately succeeded by a more intense heating in the chamber, *M*.

This chamber, *M*, lying below the hearth of the reverberatory furnace, a^x, and communicating therewith by a narrow, but sufficient passage to allow all the material which comes down through the tortuous desulphurizing passages to be discharged into the chamber, *M*, at a high temperature. The object of the chamber, *M*, and its connections is to deoxidize or chloridize the ores.

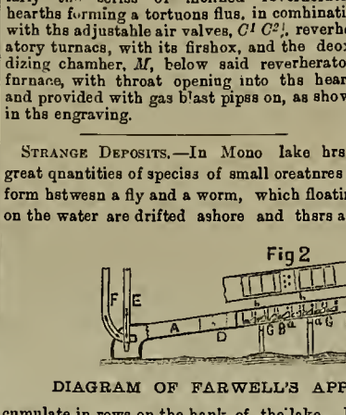
For the purpose of deoxidizing, the inventor provides a liberal supply of water gas, produced either by carrying steam through a mass of red hot charcoal, coke or coal. This gas is supplied at a high temperature through the passages, *m*, around the base of the chamber, *M*.

The water gas, or hydrogen, is presented at a high temperature to the ore in the absence of oxygen, except such as may be in the ore. The effect is to thoroughly exhaust the previously finely broken and desulphurized ore of its oxygen. The bottom opening, *b*', must be guarded to prevent access of air.

The inventor proposes in some cases, to introduce chlorine gas, as he thinks this gas will under these conditions be peculiarly useful in chloridizing ores. He says that ores containing gold and silver may be simply desulphurized and passed down into the lower chamber, where a stream of chlorine gas is allowed to act on them.

This inventor is of course aware that a series of reverberatory hearths forming a tortuous passage for ore, terminating at its lower end in a reverberatory passage, leading to a cupola below, connected near its lower end with a fire-box, has been used before. He claims particularly the series of inclined reverberatory hearths forming a tortuous flue, in combination with the adjustable air valves, C^1 C^2, reverberatory turnace, with its fire-box, and the deoxidizing chamber, *M*, below said reverberatory furnace, with throat opening into the hearth and provided with gas blast pipes on, as shown in the engraving.

Strange Deposits.—In Mono lake broad great quantities of species of small creatures in form between a fly and a worm, which floating on the water are drifted ashore and there accumulate in rows on the bank of the lake. In some places these worms have formed banks half a dozen feet thick; in fact, they have created immense deposits. This has been going on for ages, and by the aid of a powerful glass this curious formation can be distinguished two hundred feet from the present shore of the lake.



Furnace for Roasting Ores.

This goes to show that Mono was a very large body of water at one time. How many tons of worms have been carried away by Indians, and how many tons have been thrown up to become part of the natural soil, is hard to conjecture; they probably amount to some millions.

Portrait of Columbus.—A most remarkable and acceptable discovery was recently made in the Spanish Colonial Office at Madrid, of a portrait of Columbus, made when the great explorer was about 40 years of age. It represents him without any wrinkles on his broad forehead, with dark, thick hair, a brilliant eye and a beaked nose. The portrait is in perfect state of preservation, and the inscription is intact. It reads: "Columbus Lygur., novi orbis repertor." The size of the portrait is about 16x20 inches.

Assessment Work.

We are constantly in receipt of inquiries relative to the assessment work required on claims, and how long work will hold the claim from being subject to relocation. We have answered the question a number of times, but the following letter from the Commissioner of the General Land Office, dated Sept. 11, 1881, should be conclusive of the vexed question relative to assessment work when it expires and claims are subject to relocation:

> Department of the Interior,
> General Land Office,
> Washington, Sept. 12, 1881.
>
> Henry A. Bigelow, Esq., Prescott, A. T.:—Referring to your letter of July 30, 1881, I have to state that the act of Congress, approved January 22, 1880, provided that "the period within which the work required to be done annually on all unpatented mineral claims shall commence on the 1st day of January succeeding the date of location of such claim."
>
> Mining claims located on the 1st day of January, 1881, will not, therefore, be subject to relocation, by reason of non-performance of the required annual labor, until the 1st day of January, 1883. Very respectfully,
>
> N. C. McFarland, Commissioner.

A New Steamer for the Coal Trade.—The new iron steamship, *Walla Walla*, the seventh vessel built by John Roach & Sons for the Oregon Navigation Co., is now loading at New York, preparatory to her voyage thither, via Cape Horn. This steamship is 336 ft. in length and 5,000 tons displacement, built wholly of iron, in seven water-tight compartments. She is a first-class collier steamship, and will be employed in bringing coal from Puget sound to this city. She is also fitted up with a first-class cabin, and staterooms for about 30 passengers. She will take her place on the regular route with the two other colliers recently built, the *Willamette* and the *Umatilla*.

Their Idea of It.—A correspondent from the camp at Pueblo, Socorro county, New Mexico, thus describes one of the peculiarities of Eastern capitalists who visit New Mexico with an idea of buying a valuable mine for a very few dollars: "Several capitalists have visited our camp with a view of purchasing, but these gentlemen have an idea that the miner enjoys his rough fare, loves to encounter danger, and that he is working for the love of God, and are quite astonished when the proprietor will not part with a $5,000 lead for $300."

Shipments of Chrome.—A contract has been entered into between the managers of the chrome deposit in Del Norte county and the owners of the steamer *Hume*, whereby the latter is to bring to this city 1,000 tons of that material; about 70 tons of which have already been brought down. The full amount that the contract calls for will probably not be shipped before next spring.

The cost of working the copper mines of Lake Superior, Mich., varies from 11c to 23c per lb. of the ingots produced. The cost of the ingots from three of the mines for 1870 was as follows: Atlantic, 12.20; Central, 11.16; Quincy, 13.71. This is the best that either of these mines has done. Last year the Central's copper cost 11.85 to produce.

The Deadwood *Times* says the mica mines near Custer promise to be a great source of wealth to the country.

Apparatus for Hydraulic Mining.

We give on this page a diagram of an apparatus for hydraulic mining, invented by Wm. B. Farwell, of New York City. This invention relates to that class of mining where the deposits of sand, gravel or other material containing gold or silver, lies in low or level places, and where it is necessary to lift the mass of matter with which the gold or silver is mixed, and wash and carry the debris away to some other locality.

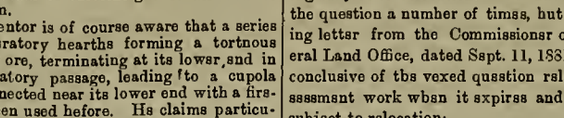


Diagram of Farwell's Apparatus for Hydraulic Mining.

In the diagram, *A* is a sluice pipe, made preferably of cast iron, and having a curved elbow at its end, opening downward and resting on the ground, where operations are to be carried on. *BB* is the ascending sluice or riffle box, and *CC* the connecting descending one. *D* is a flexible joint, made of strong canvas or other material, by which the sluice pipe, *A*, is connected with the box, *B*. This joint enables the sluice pipe, *A*, to be swung around in various positions, so as to operate over a wide surface of ground. To enhance its utility in this direction this sluice pipe may be made telescopic, if found to be desirable. *E* is the vertical pipe through which the jet of water is forced, which digs up the ground on which the open end of the sluice pipe rests, and *F* is the pipe through which the force-jet of water flows up along the ascending sluice box, carrying with it the loose gravel and the other matter dug up by the jet from the pipe, *E*. *G G* are the riffles in the ascending sluice box, showing the quicksilver lying in front of them, as at *a a*; and *b b* are the hanging spike or pin detents. *H H* are the riffles in the descending sluice box, with the hanging spike or pin, *c c*, above them. *I* is a second force-jet pipe for forcing the gravel, water, etc., up through the second ascending riffle box as fast as delivered from the descending riffle box, which arrangement may, as has already been remarked, be continued on to any required distance. The riffle boxes are supported on trestles, or in any other way that may be found economical and practicable.

It is obvious that the force water jets may be supplied by steam power or by the ordinary method of a fall from a sufficient hight to make them effective.

The inventor says he prefers to arrange the sluice at a considerable inclination, so that gravitation and the force of the current shall be in a considerable degree opposed to each other, in order that the particles of gold may all find their way to the riffles before reaching the end of the sluice. It is obvious, however, that any inclination of the sluice, however light, or even a horizontal arrangement of it, when used in connection with a forced jet of water, would secure in a beneficial degree the advantages above referred to, as the force of gravity would tend to retard rather than to hasten the passage of particles of gold through the sluice.

The first ascending sluice box may be supplied with gravel, sand, etc., containing gold, by means of a hopper, into which the material can be dumped or shoveled, as may be desired, without the intermediation of the digging jet-pipe, *E*, a single force-jet pipe, *F*, being in such case only required to carry the matter thus fed into the sluice box up over the riffles, as already described. This hopper may also be provided with a screen to prevent stones or other matter from getting into the riffle box.

The Leadville *Chronicle* says that a stop should be put to the prevailing custom of naming new mines after old ones. The habit leads to confusion, and in some cases proves a source of fraud. Several parties narrowly escaped being swindled into buying or lending money on Morning Star stock last year—the stock having no connection with the well-known Morning Star, but representing some unknown prospect at Ten Mile. Surely there are new names enough to be thought of without falling back on the old ones.

Big Bar.—The Christy Company recently shipped a bar of bullion valued at $2,799—the largest yet sent from Silver Reef District, Utah.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Butte Mountain.

Steady and Rapid Growth.

EDITORS PRESS:—This is probahly the most hnstling, overcrowded place in all the mining regions of the West. There is too mnch to be done for the money and the means at hand for doing it; too much husiness for the limited facilities we enjoy. The town now containing some 8,000 people, is a perfect jam, and more coming all the while, and this, with winter approaching, when they ought to stay away, aud when some already here will have to leave, for with lumher scarce, and supplies limited all cannot expect to get employment here during the winter. We have not hotels to accommodate, nor restaurants to feed the transient population.

Prevailing High Prices.

Merchandise, real estate and everything else here is dear. Wages of labor are also high—$3 to $4 per day. Prices are, in fact, too high to last, though not too high for present condition of things—all being alike, inflated. But these are matters that time and the railroad will regulate, for the now isolated sitnation of Butte has a good deal to do with causing and keeping up high prices. Value of bullion now being shipped from this town is $50,000 per week, and within a year will probably be three or four times tbat amount.

The Mines.

Thie rapid growth of Butte is, of course, all dne to the mines in the neighborhood of which there are many, some of great known value. I will not say as many do, that we have here the largest mines in the world nor the hest, nor will I affirm that they will rival the Comstock in production. But this may be safely said, that for the work done upon them, these mines make the hest showing of ore and give better signs of permanence than any yet developed west of the Rocky mountains. Whether larger or smaller, bettor or worse than the Comstock, these mines will have a very different history from that of the claims along the great Washoe lode. There may be gambling in stocks of theso Butte mines, but if so, there will always be bullion production and profits and that without many assessments, for after the lodes here are once opened and provided with plant, they will he self-sustaining at least, and not be constantly asking share holders to go down into their pockets to keep the life in them.

To simply name all the promising properties in this district would more than fill a column of the PRESS. Standing high up on the list of merits, are the following: First,

The Alice,

Which, so far as bullion goes, ie the leading mine in these parts, though not therefore necessarily the beet. This mine has now been opened by main shaft to a depth of over 700 ft., and hy levels run off from it every 100 ft. On most of these levels stoping is being carried on; only as much ore is being taken out, however, as the mill can handle. The quantity that conld he extracted without extra effort might be doubled if there were here meane for reducing it. The weekly product of the mine amounts to something like $30,000; monthly dividends, $40,000; total dividends dishureed to date, say, $200,000. That it can keep up this rate of production for years is here generally helieved.

Next among onr big or at least most prominent mines is the

Moulton,

On which a magnificent, first-class 40-stamp mill has just been completed and is now ready to commence running, only awaiting the finishing of the ditch for bringing in water, now nearly done. The steam hoisting works are also very complete, with lifting capacity to go down and drain the mine for 1,000 ft., or more. The main shaft having three compartments, ie now down over 500 it.; sinking, temporarily snspended, will be resumed as soon as the big pumps, now on the ground, are in place. Levels from this shaft are heing carried off every 100 ft. Every part of the mine is in the best possihle condition, and splendid ore bodies are being opened np. The work throughout is, in all respects, first-class, attesting the superior skill and good judgment of Prof. J. E. Clayton, the company's consulting engineer. This compsny, in a bnsiness point of view, is made up of exceptioually good material, the directory comprising some of the most solid men in the country.

The Belle of Butte

Is another mine that ranks high, in expectation at least, among our foremost claims. It is a live property, heing more than self-supporting even in its incipient stages of development. It has yielded high-grade ores from the start, and growe daily hetter under active working. It showe unmistakable eigns of permanency, and is held at a pretty high figure.

A Great Enterprise

Has jnst been consummated here, in the consolidation of a series of valuable claims, known as the Burnett, the Mountain and the Buffalo, formerly owned by different parties, hut eo situated that they reqnired to be exploited hy one set of works, and, therefore, to he reduced to a single ownership; an end that, after some delay and much negotiation, has at last been effected, to the great benefit of all concerned.

The company, owning a property of gigantic magnitude, and heing financislly etrong, will at once proceed to develop the same in an effective and systematic manner by means of a three-compartment shaft to he carried to the deep. In the spring a 40-stamp mill will be erected, should developments in the meantime result as expected.

Waiting for the Railroad.

Among other prominent mines here, fnrther notice of which will have to he postponed to another writing, is the Lexington Acquisition, Bell, Wahash, Morning Star, Stevens, etc., on all of which, besides many others, a grsat deal of exploratory work has been done, all exhihiting more or less good ore.

The citizens of this town and district are just now heing exercised over the question of having a railroad brought into the town. The Utah and Northern company propose to extend their road to Bntte, provided the people here will assist them to the extent of securing them right of way, station sites, etc., an object which our citizens are now considering, and which they will no doubt be ahle to carry out. Should they do so, our town will be connected with the outside world by the iron rail within the next six or eight months, securing to it and the adjacent mines many much needed and lasting advantages. NEW MONTANA.

October 5, 1881.

Bishop's Creek.

EDITORS PRESS:—Bishop's Creek is no longer the qniet farming town of former days. Its transformation has been gradual and complete. No longer do we hear at the store or the black smith's shop the price of live stock, of farm produce or agricultnral implements, discussed; hut the constant theme of conversation is the mines; and like all new mining camps, thero are among its denizens some enthusiastic creatures, who imagine that there is a fortune awaiting each and every one who may choose to take hold and develop a mine. But theirs is not an experience of long etanding; nor do many of that class "practice what they preach." They prefer to sit heneath the shade trees of town to making an honest effort toward building up a mining district.

However, there is a large number of good, practical miners, sober and industrious, who are scattered over the two mining districts, and who are slowly hut surely proving the mines of Owen's river to be something more than an illusion.

Such has been the influx of prospectors and the extent of their discoveries that at present there is a succession of camps on all the creeks and springs along the western hase of the White mountains for a distance of 20 miles, and reaching far back toward the summit.

Many of these prospectors have hut recently commenced work on these mines, while a few have reached a depth of from 30 to 70 ft. Several honded properties have reached a greater depth, and the Pajaro, now called by its incorporate name, the Poleta, has reached a depth of over 250 ft., and in no instance have I heard of the hottom being found, or a bad report given, and usually an increase in the value of the ore.

Several croppings in the vicinity of the Poleta were located, that gave no trace of gold on the surface, but at a snort distance from the surface carried an ahundance, and now are good mines, the ore assaying from $40 to $75 per ton.

A numher of mining experts have paid the districts a visit, and have invariably pronounced the outlook good, and this giving expression to a favorable opinion shows that the prejndice once existing against the mines of Owen's River, is wearing away. It cannot he many months before a mill will he erected for crushing the Poleta ore, and when that is accomplished, others will soon follow snit.

Several arastras have been running during the summer in the vicinity of the Poleta mine, and one also has been huilt in the Piute district, to work ore from the Mountain Chief, a free gold ledge discovered last June.

A town has also been laid out near the Poleta mine, given the name of Story City. Ten or 12 buildings have heen erected, among the numher a store and two ealoons.

It has been proposed, and I helieve the project is now under way, for a line of telegraph to extend from Bodie, through Owen'e valley, to Lone Pine. If this is carried ont, other improvements will soon follow.

Thus the wheels of progress are moving slowly forward, and Owen's valley may yet overflow with a population whose enterprise, hoth mining and agricultural, ehall stand second to none on the cosst. CONCORD.

Bishop's Creek, October 2, 1881.

THE Ogden *Pilot* relates this: J. Childs, better known ae Caribon, after whom the Carihou mountains were named, died at Soda springs last Saturday from the effects of a tussle with a hrown bear at Idsho Bar, Oneida county, Idsho. Carihou, who was a noted hunter and prospector, fired at and seriously wounded the hear, and with a companion plunged into the brush after his victim. The first thing Caribou's companion knew, the hear had the best of the eituation. Carihou wae literally torn to piecee before the bear was killed.

Silver District, Arizona.

From a lengthy article in the Arizons *Sentinel* we extract the following facts concerning this district:

There is positively not one ledge in thie district running athwart the conntry formation. The ore channels are four in number, viz.: The Silent channel, which is the extreme west and nearest the river, from which it is distant four miles; the Princess channel, one mile easterly; the Long, or Nine-mile channel, to the east one-half mile; and the New York channel, extreme east, distant one-half mile, a grand average over all of two miles. And this system, hear in mind, has a regular and parallel trend northwesterly and southeasterly, accompanied by huge granite mountain ranges, which form the foot-walls; and the low country hetween these huge dykes, and separating them, is of porphyry and oonstitute the hanging walls. The croppings of a volcanic trap, overlying the ledges, is of the most massive character, heing in width from 20 ft. to 200 ft., and looming up in many instances 160 ft. in height. The Nine-mile chsnnel has an unbroken hody of hnge croppinge for nine miles in length; and with a few breake (but not one blind lode), bae 32 locations on this one channel.

Now no miner will gainsay the proposition tbat I hold to, that we possess in these contact ledges, with their regular trend, parallel system and massive croppings, undoubted and true fissure-veins. And the character of the vein stuff, according to gcological lore and practical demonstration, is, heyond cavil, silver-hearing and favorable to metal at any attainable depth, consisting as it does of quartz, heavy-spar, calc-spar and fluor-spar and occasional hematite seams of ore—notably on the Klara. The greatest depth yet attained on the vertical shaft of the Silent n ine shows improvement in quantity and quality of ore in descent. No cribbing nor timhcrings are needed in development, and not a drop of mo sture is encountered at present depth, thus doing away with the expense attending a wet mine. The ore gencrally found is argentiferous galena, grey and whits carhonates, eilver glance-black sulphurets and and chlorides, about two-thirds milling ore, the remainder smelting variety. This will suffice for the ledges. In our avsilahility we are the peer of any mining camp in the Territory. The Colorado, a navigahle river, is from the district a distance of from four to eight miles. From the landings to many of the mines are good wagon-roads with easy grade, and at nominal coet can be exteuded to the others. The Territorial wagon-road now traverses the district longitndinally, thus bringing into notice eome of the most promising prospects in North Silver district, principally the Rooster, Clip, Alberta, Trne Fissure, Georgia, Marianna, City of Chicago, Joeephine, Waco, M. T. Orr, Silver Brick, Great Eastern, Great Expectatione and many others.

Tri-weekly stages run the 45 miles to Ynma, and there is also kept constantly on the road a fast freight teani, which, in connection with the regular monthly trip of the steamers on the Colorado river, give yon every facility of receiving freight and shipping ore or bullion. Telephonic communication will be had with Yuma as soon as the husiness justifies it. A eurvey has besn made, and in 30 days a narrow-guage railroad can he, and when necessary will be, huilt for transporting ore to the furnace and mills at the river and delivering water at a nominal cost. We are now paying one dollar psr barrel, with the exception of the Chicago Company, who have an exhaustless supply in a huge tank or natnral reservoir at their camp in East Silver District, annusl rains heing sufficient. Wood is abundant, delivered at the river for $3.50 per cord; wages for first class miners, $3.50 per day.

Legitimate mining is the rnle in the camp. Within the past year two large sales have heen made: The Silent mine to the R. C. G. and S. M. Co. for $100,000; the Hughes group, Black Rock, Pacific and Blue Rock mineet oa Boeton company, represented by Franklin J. Clark, for $175,000, both spot cash sales; two-thirds interest in the Silver Glance mine for $10,000; the Mandeville mine for $50,000; and it is rnmored the Clip mine will soon go at $50,000. Other sales are on the tapis. Rich strikes have heen made in the Black Rock and Pacific, the Silent, Silver Glance, Melissa, Rover, Rooster, Clip, Nellie Kenyon, Princess, Emma, Klara, Engineer, Remnant, Mamie, Iron Cap, Medora and Missouri.

LOOKING UP.—The mining outlook in all sections of our county is very encouraging at this time. From every mining camp around us comes news of the most encouraging nature. Ward, which for the past two years has heen nnder a heavy cloud, promises at an early day to again resume bullion ehipments on a permanent scale. Taylor district has already wheeled into line, and last Monday shipped its first bar. It bids fair to keep on shipping the shining metal for months to come. Silver Canyon and our own district are regular ehippere of the precious metals. Egan Canyon is getting ready to join in the chorus of the etamps and in about two months will be ready to join her sister camps in shipping bullion. White Pine, we regret to note, is the only district in our county that does not to-day show improved signs of prosperity in a mining point of view. With this solitary exception, there is a general movement for the better all along the line of the mining camps in White Pine conuty. We are pleased to note it.—*White Pine News.*

The Pioneer.

In a lecture delivered some time since by Thomss Fitch, he closed with the following glowing eulogy of the Pacific coast pioneer.

The gallant pioneer! He is tbe type of American fraternity, for be bas

> "Honor and courage;
> Qualities that eagle-plume men's souls
> And fit them for the sun."

He climbe like a huge fly upon tbe bald skull of some lofty mountain, and the primeval hills welcome his footsteps. He taps with the prospector'e pick at the adamantine doors of the earth's treasure chambers, and at his demand they reveal their shining secrets. His glittering ax lays low the green-plumed foreet monarchs, and on the emerald-hued prairies he marks the sitee of the cities yet to he. Not for him the science of the school; not for him the graces of culture; not for him the joys of home; not for him the sweet solaces of life. But he reade the story of the ages written on the rocks and hears the tale of mysterious forces whispered by the midnight stars; and the priest-robed mountains and the smiling lakes and white-lipped sunset seas are his kindred. Southward you shall behold him, undaunted by the roar of the Colorado, or and onward to listen to the wash of tropic waters. Northward his resolute face is turned toward the wooing mountains of crystal, until the north star gleams like a mighty diamond in its gold and crimson settings of northern lights, and the sudden snn hut for an instant hangs upon the verge of the polar night, a faint reminder of the lost southern clime, while the hooming artillery of the ice king hails the pioneer of polar seas. Westward—ah, there is no longer a west! The iron lace with which Progress fringes her garments reaches now to where the Golden Gate swings back upon her hinges. Asia and the Farther Indies are just beyond, and tbe Orient of Europe is the Occident of America.

And etill from the silver and the orange hlossoms of cactus-fringed aud snow-crowned Mexico, northward to where the icebergs glitter against an Arctic sky, our pioneers are marching and toiling. In the track which their fierce feet are breaking, our country is marching onward to her greatness. The army of civilization swells npon their pathway. Art, science, progress, the wealth of nations, the power and glory of the Republic follow. All honor and all hail to those brave hearts who lead the vanguard!

Tapping a Lake.

Eagle lake is located in Lassen county, Cal., 100 miles north of Rsno, and near the projected course of the Nevada and Oregon railroad. It is 30 miles long and 10 miles wide, and containe 116 square miles of water snrface. It hae no known outlet. Messrs. Marker and Merrill own the lake and many thousand acres of timher and farming land adjscent. They are now running a tunnel, which will be over 7,000 ft. long, to tap the waters of the lake at a point 12 ft. below its hed. The tunnel is now in 250 ft., and ie being pushed forward by two shifte of workmen. When the lake is reached the fall of water obtained will he used to run a sawmill and flume, which will be huilt from the mill to Belfast, 26 miles distant. The timber cut in the mill and cordwood will be floated down the flume, and its watere will further he utilized for irrigating the thousands of acres near Belfast, which need but their fertilizing touch to swell with an abundant harvest. The timber around the shores of the lake is mostly spruce, yellow pino and sugar pine. The trees are not as large in girth as those at the Truckee and Bigler woodlands, but are unusually tall and straight. The majority of the pine trees will yield four 16-foot logs hefore a limh is met. The projcct of draining the waters of such a large eheet as Eagle lake and forcing them to actually eerve as hewers of wood and cultivators of the soil, is an amhitious one and worthy of Western enterprise. There seems no reaeon why the scheme should not prove entirely successful.—*Esmeralda Herald.*

WINTER IN GUNNISON.—The season is approaching when the dwellers in the Gunnison region and those who have "stopped over" upon the reservation must provide themselves for a hard winter. This means the abandonment of surface prospecting nntil next spring. The principal mines under systematic operation, about Ruhy, Gothio and other advanced sections, can, if the owners choose, he conducted as nsual through the season, however severe it may he, if well housed, hut except where provided with smelters near at hand, they cannot market any ores. Thie will probably he the last winter of complete isolation for the Gunnison camps, because in anothcr year they will hs connected with the outside world hy railways.

STREET-CAR TRAFFIC in Philadelphia is to he changed, either hy introducing electricity or running the cars with a wire rope on the plan now on trial in Chicago. Referring to the wire-rope system, the president of one of the principle horse-car lines said, the other day: "The only thing we are waiting for is a test as to the climate. If it will etand the next wintsr in Chicago, then it will be introduced in Philadelphia next snnner.

MECHANICAL PROGRESS.

A Central Power Locomotive.

The prinoiple of the construction of the railroad locomotive, which has obtained up to the present time, has ever been considered exceedingly faulty. What is desired in a locomotive is such a construction as will admit of the motive power being located in the middle of the machine, with the center of gravity coincident with the vertical medium line of the engine. These objects being attained, it would be hardly possible to overestimate the value of the invention, since the locomotive will then be constructed upon correct principles and accordiag to natural laws. It would work from its center, with its motive power situated in a plane extending through its center of gravity, and would therefore have no dead weight. This problem seems to have been solved by Dr. Christian Rauh, of New York city. The Doctor, in order to thus definitely locate the center of gravity, has constructed his engine in such a manner that each half of the total structure, whether divided longitudinally or latsrally, is an exact counterpart or duplicate of the other half, both as regards weight or measure; the consequence of this is that the center of gravity is in the intersection of the longitudinal and transverse center plane of the entire locomotive; and by placing his motive power in the central transverse vertical plane of the engine he has disposed the parts of his locomotive to the best advantage for economy and efficiency. It has two boilers placed end to end, which extend the whole length of the locomotive. The ceb is in the center and covers the steam dome—the smoke-stack passing up through the center of the dome. The steam cylinders are vertical; they *may* be horizontal. The driving-wheels are situated equidistant from the center line. It has no tender, the water tanks being placed below the boiler, openings being made for the axles of the wheels to pass through. The fuel is carried in bunks arranged sideways and above the boiler.

The above are the main features of this novel engine, which the inventor claims as the first locomotive built upon strictly scientific principles, and the advantages claimed for it are numerous.

This engine has no dead weight, therefore its whole power can be utilized for drawing freight; and it is claimed that such a locomotive of any given size will do more work than any other locomotive of the same size under the same conditions. The heat is better utilized, as it is led back through the boiler by means of the return flues, and the fuel will be more fully consumed than it is now.

It is claimed that a train may be run at a much higher rate of speed with this engine and with much more safety than now, owing to the balanced driving wheels and the peculiar relation of the parts; and there is less danger of breaking the driving rods and less strain upon the track.

We understand that Dr. Raub is now making arrangements to build several locomotives according to his new system, of different patterns and sizes, in order to practically test their merits and superiority and to ascertain the actual percentage of saving in running them. This engine is illustrated in the *Scientific American* of the 15th inst.

Heating Steel.—Much of the difficulty experienced by machinists in occasional attempts to forge their own tools, says the *American Machinist*, comes from improperly heating the steel. To produce a good cutting tool, steel should be heated no more than is necessary to forge and temper. Follow the advice so frequently given, to heat slowly, but at the same time avoid being too long in heating. The best results are obtained by a moderate, even heat, until the proper degree is reached, and then forging at once. It is a great but common mistake to allow the piece to come to the proper heat and then lie in the fire with the blast shut off for some minutes. While this should not be done in the process of forging, the practice should be particularly guarded against when heating to harden. In the process of forging, the hammering in some degree seems to "restore" the steel; but when the tool is hardened and tempered from such a heat there is no possibility of its ever being of much use. In tempering, the drawing should be done quite slowly, as in this way a much better cutting tool is produced than when it is rapidly performed. The color is by no means a sure test of temper, since different kinds of steel do not take the same color for equal degrees of hardness. This is also true of steel that has been worked considerably, as old tools. The only guide in this respect is experience and judgment. Steel tools should never be heated, either for forging or tempering, in a fresh coal fire (unless it be charcoal). If coke is not at hand the fire should be allowed to burn until the gas is burned out of the coal, before the steel is introduced. What has been said in reference to heating steel for cutting tools is equally applicable to steel used in making springs.

How to Use a Cold Chisel.—Hold the instrument firmly to its cut without removing it at every blow. This will increase the effectiveness of the tool, and there will be less danger of breaking by a foul blow.

File Sharpening by the Sand Blast.

Among the various methods that have been tried to sharpen files, says the *Blacksmith and Wheelwright*, none can be said to be really successful but the sand-blast process. This consists in forcing a jet of fine sand at a high velocity against the backs of the teeth of the files, which cuts away the worn edges and leaves the file sharper than when new.

In explanation of this fact, it may be stated that it is well known that any fine edge is dulled to some extent if it is afterward heated to harden it. Furthermore, there is in new file teeth a burr that is more or less rounded, according to the sharpness of the file cutter's chisel, and this rounded burr the sand reduces to a plane, leaving a sharp cutting edge.

From some experiments that have been made, it was shown that a sand-blast file removed with the same number of file strokes (1,200) twice the amount of iron that a new file did.

It takes from two to five minutes (according to hardness, size, etc.) to sharpen a file by the sand blast, and each file may be sharpened a number of times.

This process possesses several advantages that are of great importance. Thus the softening and rehardening necessary to recut files damages the steel. In grinding out the old teeth the file is thinned and care is not taken to make the curve of even sweep. Indeed a recut file can be told because this taag shows its undue thickness. Whereas, in a sand-blast sharpened file no warpage and no reduction of thickness occurs. Hence the file retains its original and correct shape.

There is no need to lose time by using files that do not cut freely because we dislike to throw them aside as long as there is any cut to them. This process is as applicable to the finest of cut files and is already in use by some of the largest firms in the country, while from its simplicity and efficiency it must eventually be found in every workshop wherein files are used to any extent.

The *Blacksmith and Wheelwright* gives an illustration of a very simple machine, the cost of which can be but little and which may be operated in any shop, by which both sides of this file, large or small, may be sharpened simultaneously.

Names of Steel.

To the ordinary reader, the numerous names applied to steel are simply bewildering. He reads articles discussing the qualities of this most useful material, and encounters name after name which, conveying no definite idea to his mind, serve to increase his perplexity. They often leave him in doubt upon important points. It is true that writers occasionally stop to define a term, or describe the peculiar qualities and nature of the steel to which a certain name is given, but at the next moment they employ terms, by way of comparison or enumeration, which they assume the reader knows, because they have been before the public for a considerable period. This leaves him almost as badly off as though none of the names had been explained. The truth of the matter is, that owing to the numerous new processes and improvements in the manufacture of steel which have been introduced recently, the vocabulary has become greatly extended. The terms which were common a few years ago have become practically obsolete, or if now used are employed in a different sense from that to which our older mechanics became accustomed when learning their trades. A brief account of some of the most common names in use at present will be of service.

Blister steel is made by causing the carbon of charcoal to penetrate iron in a heated state. German steel is blister steel rolled down into bars. Sheet steel is made by hammering blister steel. Double shear steel is made by cutting up blister steel and putting it together and hammering again. Crucible steel is made by melting in a pot blister steel and wrought iron or unwrought iron and charcoal and scrap. Bessemer steel is made by blowing air through cast iron, burning out the silicon and carbon. Open hearth steel is made by melting pig iron and mixing wrought iron, or scrap steel, or iron ore to reduce the silicon and carbon.—*Blacksmith and Wheelwright.*

Phosphor Lead Bronze.—Mr. Moss, of Cheapside, London, is introducing a new alloy into the market, which is said to possess great strength and resistance to the effects of friction. The advantages claimed for phosphor lead bronze are—self-lubricating properties, tenfold wearing capacity of any other metal or alloy, great tensile strength combined with extreme hardness, non-liability to fracture, keeps perfectly cool under continuous and excessive friction. These qualities, it need hardly be said, are those most necessary for bearings and bushes of every description, guide blocks, slide valves and faces, piston rings, pinions, valves, etc.

The Temper of Steel, it is generally held is due to the chemical union of the iron with the carbon. At low temperatures this union seems to take place only in a slight degree, and hence in soft steel we have the carbon keeping aloof from the iron; but as the temperature is raised, the combination is more perfect, until, in the case of grey or glass hard steel we have really a kind of artificial diamond alloyed with iron. In all cases sudden cooling is necessary to fix the combination.

SCIENTIFIC PROGRESS.

Chemical Storage of Heat.

An invention of quite an interesting character has recently been made, in which the acetate of soda forms the chief factor. This invention, when divested of scientific language, may be stated to consist of the property of the acetate to absorb heat when subjected to it for some time, and then to give it out afterward over a prolonged period—in effect to store up heat, which, owing to crystalline changes during the act of cooling, is continued to be evolved from the latent into an active form. That this is the case is indicated by the fact that the vessel containing the salt, after having been removed from the source of heat for two hours, has its temperature raised about 6° Fahr. during the third hour by its own inner forces alone.

The physical principle upon which this curious invention is based is old and well known, although the application of the principle is novel. The form in which we have obtained a specimen "heater" consists of a somewhat large flask formed of thin sheet brass having its mouth soldered up, for it is never intended to be opened. There is also a metallic loop by which to suspend it in the vessel of boiling water from which it is to derive its store of heat. The length of time required for immersion in the hot water depends upon the size of the heater; for example, if it be so small as to be suitable for being carried in a lady's muff, by which to keep her hands warm, four or five minutes will suffice; but if, on the other hand, the dimensions be such as enact the part of a foot-warmer, this time would have to be increased by six or eight times. There are some so large as to require immersion in boiling water for an hour before they are fully charged with all the heat they are capable of storing.

While the length of time over which heat is given out depends entirely upon the dimensions of the flask containing the acetate of soda, it may be roughly estimated as about four times as long as hot water will retain its heat. This most sudden fall takes place during the first two hours, after which the temperature rises a few degrees, gradually subsiding until it becomes quite cold.

Influence of Magnetism on the Electro-Deposition of Metals.—Prof. Ira Remsen, of the John Hopkins University of Baltimore, has lately made some curious and instructive experiments, to determine whether the chemical behavior of a metal was in any way influenced by magnetic action. The results which he obtained were very interesting. Very striking effects were obtained by bringing a thin, shallow iron vessel, containing copper sulphate in solution, over the poles of a permanent magnet. Out of the magnetic field, the solution would deposit copper uniformly over the surface of the vessel; but in the field, the lines marking the poles were sharply defined as depressions in the deposit. With an electro-magnet the effects were still more noticeable. In the limited space marking the outline of the poles there was no deposit of copper; within this the deposit was fairly uniform, but outside, the copper was deposited in irregular ridges running at right angles to the lines of force, and apparently coincident with the lines marking the equi-potential surfaces. When the power of the electro-magnet was increased, the effects above noted were intensified and the area affected was broadened. These experiments open up a novel field of inquiry, and may in time result in important applications.

Engraving by Electricity.—M. Plante has succeeded in obtaining engravings on glass by the following process: The glass is laid in a horizontal position in a shallow vessel and covered with a concentrated solution of nitrate of potash. A platinum wire is dipped in a horizontal position in the solution along the edges of the glass. The platinum wire is in communication with one of the poles of a secondary battery of 50 to 60 elements. The lines are traced by hand with the point of an insulated platinum wire, which is in communication with the other pole of the battery. The parts of the glass covered with the alkaline solution become engraved when touched with the end of the platinum wire, however rapidly this is moved, the thickness of the lines varying with the thickness of the wire. The current from either pole can be led into the writing wire; that from the positive pole requires, however, a stronger current.

Colored Photographs.—How photography of colors may be accomplished by dying layers of coagulated albumen was lately explained to the French Academy of Science by C. Crose and J. Carpentier. They submitted two photographic proofs of a painting in water colors along with the original, showing the exact reproduction of the details and colors. Three photographs of the original were taken—one through a liquid orange screen, another through a liquid green screen, and a third through a liquid violet screen. For the image obtained through the first screen, a red color bath was employed; for that produced through the second screen, a blue bath; and for that effected through the third screen, a yellow bath. In this process there is evidently no direct photographic reproduction of objects with their natural colors.

The Value of Science.—Mr. J. D. Cox, ex-Secretary of the Interior, in the course of his address of welcome to the American Association for the Advancement of Science, at its late meeting in Cincinnati, remarked as follows: "Science is not without interest to all classes, and has a natural relation to business centers and economics. Science must be sought for its own sake, as all that is valuable in knowledge goes to complete the man. Since the first meeting of this association, more wonderful revolutions have taken place in the history of progress than ever in the same period before, and the triumphs of science are more marked. A scientific association is not for the profit of a business venture or for personal aggrandizement. The true fire of scientific zeal will rise into the domain of devotion, a devotion to science for its own sake, to an object worthy of its labor and higher than the accumulation of wealth. Some one has said, 'There is a natural tendency to give too much importance to a special department in science.' We need to concentrate all that makes intellect broad and ennobles soul-life."

A New Carbon for the Electric Light.—The waste of vegetable ivory placed in a lated retort and subjected to a cherry-red heat for three hours, is subsequently ground to a fine powder, mixed with a "suitable paste" and subjected in molds to heavy hydraulic pressure. The product of these operations is said to be superior to retort carbon for electric candles and probably also for batteries. The inventor, Mr. C. M. Ball, of Troy, thinks that his process is "going to revolutionize electric lighting."

New Thermograph.—Dr. W. D. Bowkott has invented, says the *Mechanical World*, a new instrument for recording changes of temperature as measured by the action of heat upon a bellow circular metallic ring connected with a circular vessel, the whole being filled with a fluid and hermetically sealed. One end of the ring is fixed, the other free to move, and the amount of motion is magnified and measured by a series of levers, one end of which carries the recording pen. Increments of heat cause increments of pressure in the ring, which, as in Bourdon's pressure gauge, then moves at its free end. The instrument had been largely used by Dr. Bowkett in the Leeds Fever Hospital for clinical purposes, but it was also adapted for many purposes of chemical and physical research.

Liquid Sugar.—Messrs. Sachenroeder & Gottfried, of Leipsic, have lately patented a process for obtaining liquid sugar which does not crystallize. Raw sugar with a high polarimetric power is clarified with a sugar solution, then passed through the Boegel turbine, and in this apparatus it is again clarified with steam, its polarization being brought to about 100°. The pure product thus obtained is dissolved in a boiler heated by steam, then passed through a system of charcoal filters, in which it becomes perfectly clear. In the vacuum apparatus the solution is reduced to 40° B., after the addition of one-fourth to one-fifth per cent. of chemically-pure crystallized citric acid or crystallized tartaric acid. The acid combines with the sugar, and deprives it of its tendency to crystallize.

Encke's Comet.—This well-known comet is now in a favorable position for observation. On Thursday last, October 20th, it was in right ascension 9 hours, 31 minutes + 19° 59', or about 4° north of Beta Leonis. It is moving a very little south of east at the rate of about three degrees daily. This has the shortest period of any known comet, making its revolution about the sun once in about 3½ years. It has no tail, but presents to the observer a flat, round disk, slightly condensed near one edge, while upon the opposite it has an ill-defined, brush-like appearance. It may be distinctly seen with a 2½ or 3-inch glass, and is quite a bright object when viewed through a 5-inch glass.

Magnesia from Sea Water.—M. Schlesing extracts magnesia from sea water by the following method: The magnesia is precipitated from the sea water by means of lime. One cubic meter of water, when thus treated and left to rest for one day, gives about 16 gallons of gelatinous precipitate of magnesia. If this precipitate is mixed with a weak solution of phosphoric acid, a precipitate of trihasic phosphate is obtained, which settles when left to rest, and can be filtered and used for the precipitation of ammonia from sewage by the methods already known.

The British Science Association recently held its fiftieth annual meeting at York. The occasion was made a jubilee gathering, and one of its most interesting features was a loan collection, in which the instruments of scientific research used half a century ago were contrasted with those now in use, with as complete a chain of intermediate links as far as could be obtained.

Grass Fired by a Meteorite.—A fire ball was seen to fall at Springfield, Ill., about 10 o'clock of the night of September 21st. It resembled in appearance an electric light, and it fell with a rushing sound like that of a skyrocket. The dry grass was set on fire where it struck, and the grass burned to a wooden sidewalk connecting with fences and wooden buildings, before the fire could be extinguished with water.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Suffolk M. Co.—Oct. 7. Location, Sierra and Plumas counties. Capital stock, $300,000. Directors—Edward Cunningbnm, J. H. Hyman, J. C. Lyman, D. O. Clark and J. C. Watson.

Gibraltar Con. M. Co.—Oct 9. Sierra Co , Cal. Capital stock, $200,000. Directors—H. J. Wilsdorff, M. Burth, P. Dolan, H. White and F. Becker.

Bush Creek M. & M. Co.—Oct. 9. Sierra Co., Cal. Capital stock, $3,500,000. Directors—A. Bateman, H. H. Pearson, Wm. Thomas, A. C. Wightman, S. E. Olmsted.

Humboldt M. & M. Co.—Oct. 12. Aurora, Nev. Capital stock, $10,000,000. Directors—J. D. Fry, C. H. Fish, G. W. Horkins, S. B. Boswell and B. G. Blasdel.

Gold Canyon M. Co.—Oct. 11. Sierra Co, Cal. Capital stock, $1,000,000. Directors—D. R. McKilican, C. Haight, F. Underhill, E. Greenbaum and F. A. Berlin..

Santa Gertrudes G. & S. M. Co.—Oct. 13. Capital stock, $10,000,000. Directors—John H. Dickinson, W. P. Willard, John Crocker, W. H. Talbot, H. H. Hubbard.

Quijotoa M. Co.—Oct. 14. Pima Co., Arizona. Capital stock, $10,000,000. Directors—Wm. S. Wood, Robert N. Graves, Wm. S. Lyle, D. M. Tyrrell, Chas H. Fish. The Gesco Mining Co. has also incorporated to operate in the same place, with the same officers.

The Contention Con. M. Co.—Oct. 10. Tombstone district, Arizona. Capital stock, $12,500,000. Directors—W. F. Dean, W. S. Hobart, Geo. I. Ives, D. A. Jenmngs, I. L. Requa.

The Mining Share Market.

Stocks througbout the week, though moderately active, have been without material variations in price. The attendance at the Board has also diminished and the volume of bnsiness done by the legitimate trade been gradnally curtailed of late, leaving transactions mostly in the hands of "chippers in" and carbstone brokers.

Meantime the Comstock press continues to describe with accnstomed volnbility the work in progress on the "great non-productive," after the manner of those who are said to "darken council with language." This thing, tbougb getting to be a little monotonous, is, nnder the circumstances, all that can probably be done.

The Californian.—The *Californian* is proceeding commendably and brings ont an excellent collection of original articles eacb month. There are now two noble serials running, one by Joaquin Miller, entitled "One of the World Builders," with its scene in the mining camps in the early days, the other, "At Cobweb and Crusty," by Leonard Kip. C. H. Shinn has a little dash of poetical prose about the garden, and Hon. B. B. Redding places upon record some interesting observations about California Indians and their food. There are several otber excellent articles in the November issne which appears this week.

It is rumored that with the proceeds of sale of all bis interests in the Iron Silver mine, Levi Z. Leiter, of Chicago, has made Judge Hilton an offer for all the dry goods business of A. T. Stewart & Co. Mines are profitable occasionally.

Comstock Lexicon.

Phrasee and Sentiments Peculiar to Stock Operators.

Eastern jonrnals devoted to stock matters use every possible effort to keep their readers posted on the jargon of the street, and publish definitions of words and phrasos cnrrent among the speculators of Wall and Broad streets, the Chicago and St. Lonis Chambers of Commerce, etc. The idea is worthy of adoption here, and as an initial step the *Chronicle* submits the following carefully compiled "Lexicon of the Comstock:"

Bear Market—So called because operators have to "grin and bear it."

To Sell Short—To promise to deliver what you haven't got. Often adopted ontside of stocks, with a paralyzing effect on credulous creditors.

To Cover One's Shorts—Generally, to buy at a big loss.

A Call—Tbis, from your broker, generally means "More mud."

More Mud—A peremptory demand that the unhappy pnrchaser sball wallow more deeply in the financial slough of despond.

Curbstone Brokers—Men who rule the market—in their minds, and always have millions—to get.

Corners—Expressive of the tight pinch given short sellers on an oversold market.

Highest Quotations—What buyers pay for stock.

Lowest Quotations—What sellers get for sbares.

Commissions—Net gains on stock operations exclusively belonging to the brokers.

Carrying Stock—Packing it from one broker to make good your overdraft with another.

Flyer—A clever little operation on the side, which generally bursts the main game.

Limited Order—Five shares at one fell swoop—largely in vogue on the Comstock.

Put—Tbe privelege of going througb and "staying out."

Margins—What operators say they will never buy on and always do.

Milking the Street—A dairy operation not attempted on C street—only appropriate for experienced pullers at the stock teat.—*Virginia (Nev.) Chronicle.*

Jumped Claims.—One of the ablest of the United Statcs District Judges of Colorado, in prononncing a recent decision upon a jumped claim, used the following langnage, substantially: "The law supposes or takes for granted that whero a man puts $100 worth of work on a claim or location, that mineral was there to justify the expenditure, or else a man wonld not be foolish enongb to put his time or money to snch a nse; and no man has the right to go on the claim of another and break the surface ground to prospect. In other words, the law accepts the acts of a miner or prospector in good faitb, and his fellowmen should do the same and keep their hands off."

Mining Summary.

The following is mostly condonsed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Mining Notes.—*Ledger*, Oct. 15: All the miners are waiting for rain. The Golden Gate is running at present. The stockholders in the Welch Hill Tunnel Co. have strong hopes of something very fine in their undertaking. The Zeile mine gives employment to about 60 miners, divided into two shifts of 10 hours each. Milling ore is extracted from the 240, 400 and 600 levels, and there is sufficient rock in sight to last for years. The quality of the ore is not definitely known, but the general impression is that the chief dependence is on the sulphurets, which are produced in large quantities, and rich in quality. The amount of free gold turned out is probably small, but the sulphurets alone are perhaps rich enough to pay all working expenses. The Modoc mine in Pioneer district, has just had 100 tons of ore crushed at Mace's mill. The yield is said to be satisfactory. Fifty tons more are to be put through immediately.

Manganese.—The character of the ore now being sent to the mill is a great improvement upon the rock crushed for months past. The shaft has been drained of water, and the workmen have been enabled to get at the 600 level, where quartz of the richest description was known to exist. It is from this portion of the mine that the bulk of the millling ore is now being taken.

Empire.—A rich body of ore has lately been struck in this mine nt the 1200 level. Owing to the scarcity of the water supply, tbe mill is at present being run entirely by steam power.

Pacific.—The shaft of the Pacific mine, at Plymouth, is down 1,000 ft, at which point they propose to commence drifting for the ledge which will no doubt be struck in a few hundred ft. The frame work of the new mill is nearly completed, and all will soon be in readiness for operation. The pipe leading from the Amador canal, for conducting water to this mine, is now being lain across Amador, Rancheria and Dry creeks.

Work has been commenced in good earnest, on the Oswega claim, about one mile nortb of Plymouth. It is believed that this will provo a valuable property when more fully developed.

The Tallsman mill, near Amador City, which has been lying idle for some time past, has again been put in running condition, and is crushing rock from a mine back of the Keystone, which is being prospected by a San Francisco company.

Sinking on the Golden Gate mine at Volcano is progressing finely, and the ledge maintains its regular width and thickness. The Downs mill of the same place is still idle, owing to a want of water.

A Dead Property.—The old Oncida mine, near Jackson, is evidently a thing of the past. Everything around the old works is as dead as can be. Nothing of any valuo is being allowed to remain on the premisos. So far as appearances go, there is a total abandonment of the mine.

CALAVERAS.

Mining about West Point.—*Chronicle*, Oct. 15: Mining about this town was never in a better condition than at present, more tban 20 mines being worked by Companies belonging to the place. Among the claims most actively worked are the following: The Pride of Bummerville, running night and day, bas a 2-ft ledge which pays $60 per tou. Ten tons on the dump, and only 40 ft deep. Sacramento is running two shifts, with 10 tons of rock on the dump which will pay $60 per ton. The lode is 2 ft wide. Present depth of shaft about 120 feet. Old French Lode is also turning out precious metal again. McClane & Co. are taking out rich rock on the Old Whisky Lode. The best ore milled paid $50 per ton. The Riverside has about 50 tons of rock on the dump, 20 tons of which will pay $100 per ton, and the rest about $20 per ton. Intend to commence crushing shortly. The Lone Star is again being worked, taking out quartz that will pay $150 per ton. Has 400 tons on the dump that will pay $12 per ton. The owners intend, when they have out 1,000 tons of such rock, to erect a mill near the mine. Keltz & Block have out about 20 tons of rock from the Constitution mine, which will pay 1 oz. per cargo, or nearly $120 per ton. Intend to crush in the near future. Champion mine is at present over 700 ft deep and still sinking on rich rock. Rose & Jenkins are taking out rich rock from the Henry mine, 120 ft deep, about 2 ft of good ore. Sixty tons on the dump which, by a proper process of milling, ought to pay $80 per ton. The owners have leased the chlorination mill for a short time and intend making nlterations therein preparatory to working a few tons of their heavy sulphuretted quartz. Ferguson & Co. are still running levels on the Florida mine, with rich quartz still ahead, plenty of gold to be seen with the naked eye. They deserve success as the pioneers of the compressed air drill in this mining district. Moore & Co. have struck a large chimney of good quartz on the Bowers mine. T. & W. Proteus have commenced sinking on the old Colorado and have struck a vein 20 inches wide, the ore in which prospects $40 per ton, free milling. G. Brown & Co. recently struck a good lode near the stage road at Sandy Gulch. Rock crushed paid $60 oer ton. Mr. C. Bailey has leased the quartz mill owned by A. M. Harris, and has put it in first-class order for crushing. The Jacobs mine is having a tunnel run on it which will tap the lode about 90 ft below the old works, and thoroughly prospect it. This mine was worked in early days down to hard ground and water. Width of lode about 20 inches. The rock taken above paid $60 per ton. The Pride of the West owned by Sterling & Co., is having a large timbered shaft put down on it. There have been some new strikes in placer mining up on the South Fork of the Middle Fork of the Mokelumne river. A number of "bars" in the river have been found which prospect 4 cents to the pan. Stephens & Co. have also struck rich gravel under the lava bed on the road to Anderson Flat, which is very extensive and prospects well.

Insufficient Machinery.—The Chapman mine, 2½ miles from Railroad Flat, bas been forced to shut down, the pumping machinery at present in uso being incapable of handling the water. In drifting north on the 200 level they cut through a large body of very rich ore, not a pound of which bas been stoped out. It is the intention of the company to sink and drift, cutting this ore body at a depth of 200 ft below the present workings, as soon as machinery is in place capable of handling the water. This is one of the best mines in that section of country, not a pound of waste rock ever having been taken out of the mine.

EL DORADO.

Grizzly Flat.—*Mountain Democrat*, Oct. 15: The Melton mill has been completed, and in a few days will start up on one of Driesbach's mines, from which good results are assured. Mr. Bullard of the Sacramento mine, will soon have his mill ready to run. He is working a large force of hands on it. Mr. Spencer, of the Grouse Gulch mine, has his hoisting works about completed, and in a few days will begin sinking, and will also commence putting up a new mill quite soon. The contractors on the Treat mine have about half finished their contract. At the Mount Pleasant mino work is being actively prosecuted on the new mill and hoisting works. The Arctic mill is running steadily on good ore from the Polar mine. Mr. Sam Davis, Superintendent of the Arctic and Eagle mines, is expected back from Sacramento in a few days, to start the Eagle mine up. Mr. Smith, lately from Mount Pleasant, Iowa, has discovered a very rich ledge near town, 7 feet wide, and the ore yields very rich prospects.

Rosebrans.—Fine hoisting works have been put up on thia mine, and underground worka are being proaccuted night and day. At the 130 level they have run 220 ft on the vein, milling every pound of rock that haa come out, and all of it has paid. For this entire distance the lode

has held its size of 3½ ft, and it is predicted that the pay chute is fully 900 ft in length. The fact that all of the rock from 220 ft of tunnel has been milled, and has paid well for milling, is sufficient to entitle the Rockrams to a front rank among the best of California quartz properties.

INYO.

PANAMINT.—*Independent*, Oct. 18: It is stated that Supt. Phelps, of the Inyo Con. Co.'s works, at Panamint, left New York for this coast on the 4th inst., "duly prepared for vigorous work." This will be good news for that camp. It is also stated that Senator Jones is going to look after mail facilities.

REX MONTIS.—Sup. Holt has the Rex Montis mill repaired, and was to start up on the 12th. A run will be made on a large amount of old tailings.

BISHOP.—The mining interests of Bishop Creek continue on the up grade. The Polete and Red Cloud are considered a fixed fact and several of the prospects on the hill are looking well.

MARIPOSA.

THOMAS THOMPSON.—*Gazette*, Oct. 15: The last clean-up here from an arastra paid $153 to the ton. The vein is mostly of decomposed matter similar to the Diltz. A small engine and two stamps are being put up, which will enable its owners to crush about two tons a day. The mine is prospected by a tunnel about 100 ft in length, and the shaft is down some 50 ft. This mine is situated on the northerly slope of the mountain at the head of Cathey's valley, and about one quarter of a mile westerly of the wagon road leading from Agua Frio to Cathey's valley.

DILTZ MINE.—At the bottom of the shaft, now 75 ft deep, a fine body of ore has been struck. This last discovery, shows conclusively that the main lead of ore, which has been the principal feeder of all this section, lies in the course of the shaft and level running northerly. Although Mr. Diltz works but a limited force of men upon his mine, every week as he progresses in developing shows the permaneucy and richness of this mine.

MONO.

THE GREAT SIERRA OF TIOGA.—*Free Press*, Oct. 18: The new double-compartment shaft is now down 87 ft; 7 ft have been added since last report. Have finished timbering the shaft. The ledge is pitching so much to the west that it has left the shaft, but a new spur has been encountered. Will be ready to cross-cut on the 10th inst. The boarding-house, shaft-house and blacksmith-shop are all up, and the gallows frame, 21 ft, 6 inches in hight, is now ready for machinery. The pack mules are still busy getting in supplies.

SQUAWVINE HYDRAULIC.—Stewart & Taylor, the owners of the Squawvine hydraulic mine in the old Mono diggings, are meet ng with great success by their enterprise. The mine is situated a short distance west southwest from the old Sinnamon cut. They have in 300 ft of pipe, with 75 ft fall, and 175 ft of sluices in place. A cut 15 ft in width, follows the bedrock in for a distance of 40 ft, and this gives a bank or face of gravel 20 ft high, 17 ft of which is pay dirt. The tunnel run into this mass gives prospects of from 2 to 8 ounces to the pan. They have a head of 100 inches of water, but the cold frequently reduces this to 80 inches.

ITEMS.—Good looking quartz has been found about the head of Virginia creek. Work has been resumed on the 1000 level of the Standard. In two or three weeks the sound of the locomotive will be heard in Bodie. The Addenda mine is prospecting well.

NEVADA.

WORK FOR ALL.—*Transcript*, Oct. 13: Since the hydraulic mines re-commenced operations the hundreds of men who were thrown out of employment when operations were suspended, and did not possess the means to get away, have gone to their old places once more. Those who left the county at the time are gradually drifting back again. Employment is found for all worthy applicants, and the demand is much greater than the supply at present. The force at one of the mines will be increased some 500 men within the next 30 days. The best part of all is, that Chinamen cannot obtain work of any kind. Everybody at North Bloomfield is happy. The people who, a fortnight ago, were despondent, are now contented with the prospect of a prosperous winter. The merchants are laying in an immense stock of goods.

BANNER.—An interest in the Banner quartz mine of this district has recently been disposed of to obtain additional working capital, and the development of the property will now progress on a much more extensive scale than heretofore. A new 12-inch Corliss engine, with heavier hoisting and pumping machinery, has been ordered to take the place of the present plant. The incline, now 280 ft deep, will be enlarged so as to have three compartments, and then be sunk to a depth of 800 ft before drifting for the Golconda chute, which was many years ago worked to a depth of 300 ft, and yielded $750,000. It is now more than a year since work was begun on the claim, and the developments have been such as to demonstrate that the chute extends ou downward from the point where the old company quit work ou it, but that the purchase of more powerful machinery will be necessary in order to open it. The tunnel recently run will drain the mine to a depth of 100 ft, thus relieving the pumps of the surface water.

RICH STRIKE.—The Los Angeles Co., on Fall creek, 27 miles northeast of Nevada City, recently started a tunnel into the bank, and after running a short distance struck in a very rich gravel deposit. Many large nuggets are found, one of them being valued at $400. An experienced miner, "Sir" John Lyons, is in charge of the property. When work was started there is said that some of the old miners in Washington township had lots of fun about the idea of going to such a spot to look for auriferous channel. Now the laugh is on the other side of the house. This new bonanza is just above the old King claim, where some 20 years ago George King (now dead), and Joe Freeman took out $110,000, or thereabouts.

VARIOUS MINES.—Souchet, quartz, still running with favorable outlook. The new shaft on the Derbec has reached bedrock, at a depth of 247 ft. It will have to be put down 38 ft further to reach the old workings. Sixty white men are working at the Malakoff hydraulic; 40 to 60 more will be put on within the next 30 days. No Chinese need apply. The tunnel of the Chapman ranch mine is now in 80 ft or more. A stringer of good quartz was struck Wednesday, and it is anticipated that the main lead will be opened on within a distance of 25 ft more. Then the force of workmen will be increased, and drifting in both directions will begin.

PLACER.

MINARICA MINE.—*Herald*, Oct. 15: Since the purchase of this mine last spring by Eastern gentlemen, work has progressed on it steadily, and some very satisfactory developments have been made. A tunnel is now in about 300 ft, and for the whole distance the ore vein maintains a width of from 14 to 24 inches. The pay chute is believed to extend the entire distance of the tunnel, and possibly, much farther, since all the ore taken out along the line has been of high grade. From near the end of the tunnel an air shaft has been raised some 90 ft to the surface, by means of which the mine is thoroughly ventilated. About 250 ft from the mouth a winze has been sunk to a depth of 50 ft, and the size of the vein and the encouraging character of the ore are maintained to the very bottom. At present the force is engaged in stoping out the ore above the tunnel. It being only a few hundred feet from the mouth of the tunnel to Pelster's mill, a tramway is being built from the mine to the mill, with the view of running the ore on hand-cars directly to the batteries, and thus obviate the expenses of extra handling. The crushings thus far under the new management, have been quite satisfactory. Expect to crush from 75 to 100 tons the present month.

THE HUNTER MINE.—T. J. Hunter is steadily at work developing his mine on North Ravine, and has obtained some satisfactory prospects. He has sunk a working shaft which thoroughly ventilates the works, and has now a force of men driving ahead in the main drift. This ledge is of good size, and the rock thus far taken out has been, on an average, very rich.

PLUMAS.

CHEROKEE MINE.—*Greenville Bulletin*, Oct 12: The shaft is 204 ft deep to the ledge lately struck; which latter maintains an average width of 3 ft, all pay as far as opened—some 30 ft on the line of the vein. The vein proper is from 5 to 6 ft in width between walls, but where first cut the pay ledge does not occupy the whole width of the fissure. The ore is rich in fine free gold, some portions of it being remarkably so, for this locality, and none of it is barren. It is confidently expected that the ledge will entirely fill the fissure when a point has been reached a little farther west; this will make a very fine body of ore.

SAN DIEGO.

JULIAN DISTRICT.—*News*, Oct. 14: The mines are all doing something better, and here there is a hopeful feeling prevailing with both the miner and the farmer. A Spanish man discovered, on Sunday last, near Julian, what is believed to be one of the richest ledges yet found in the district, being wider than most ledges in the mining belt there. It will be worked immediately, and if it proves as rich as supposed, will help the section vastly, as all will get something from it.

SIERRA.

DRIFT.—*Mountain Messenger*, Oct. 15: Four men took out 60 ozs. from the Bald Mountain Extension mine at Forest City, last week, no more being able to work underground on account of impure air. In three weeks, when the new air-pipe is laid in the main tunnel, Superintendent Lawry says he can put on at least 50 men. Total yield of mine since first prospect, near face of main tunnel, $7,000. The prospect is now that no more assessments will be levied. Up to Tuesday night, 31 ozs. were taken out this week.

NEVADA.

CHERRY CREEK DISTRICT.

MAKING BULLION.—*News*, Oct. 15: The Star mill, since the recent repairs, is doing good work. Supt. Foulke informs us he feels confident he will be able to run 750 tons per month through the mill, being 150 tons more than was ever handled before in the same time. He expects to turn out bullion to the value of $40,000 to $45,000 per month. The mine is looking well, and has more ore in sight to-day than ever before. The work of sinking the shaft is progressing satisfactorily.

MARTIN WHITE.—Supt. Sweetapple writes the company as follows: Getting on well with the work in the raise, preparing it to receive all the waste from above, and in a day or two will have the air pipe secured against danger from falling rocks, etc. Have air enough in the mine now and are putting in doors in the tunnel to check the current which is too strong for comfort in working. Shall not attempt to do any work in the way of opening up until I get all this work completed, as the men would only be working against each other.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, Oct. 15: During the past week the mine has shown no change of importance. The shaft levels present about the same appearance as at time of last report. There is some improvement in the 12th, where the ore is of fair grade and shows a vein 2 ft in width. The 10th and 11th are looking and yielding as usual. The levels above present no change worthy of note. There are being extracted and sent to the mills about 36 tons of ore daily. Mill No. 1 is running steadily. Mill No. 2 was stopped on the 10th inst. for repairs, but will start up again early next week. Bullion shipments for the week ending Oct. 12th, $23,578 52. Shipments on October account to Oct. 12th, $30,693 05.

MOUNT COREY MINES.—About 35 men are at work in the camp. The town boasts a store, blacksmith shop, lodging house, boarding house and a saloon. The little 8-stamp mill is getting away with 8 to 10 tons of Big Injun ore daily. The ore has to be hauled about three-quarters of a mile. Many claims are being opened, and the prospects are accounted good.

MARIETTA.—In this town, which for a long time before was extremely dull, business has undergone some improvement of late owing to a somewhat better outlook in the neighboring mines.

EUREKA DISTRICT.

STRIKE.—*Sentinel*, Oct. 13: The Monument Tunnel Co. have struck an immense body of galena ore. As yet there have been no assays made of it, but the indications are that it is a rich find. It is seldom that a tunnel enterprise starts out with such encouraging prospects.

A NEW TUNNEL.—A survey has just been completed at the Geddes & Bertrand for a tunnel from the mill to the 300 level of the mine. The tunnel will be 500 or 600 ft in length, and when completed the ore will be run through it instead of being hoisted up through the shaft.

ESMERALDA DISTRICT.

THE CORTEZ.—*Herald*, Oct. 15: Face of the lower tunnel here is in better working ground and good headway is being made. The drifts and incline show splendid ore and in large quantities.

SWEETWATER MINES.—Great Western shows improvement within the last week. The face of the drift north from the tunnel, now in about 40 ft on the ledge, shows fine milling ore. The lower tunnel is in about 20 ft and has struck the first ledge, which contains excellent ore. The Somers is being developed as rapidly as men and means can do it. The main tunnel runs north; about 60 ft from the mouth a cross cut was run west which cut the ledge. Ore found of high grade. Ledge about 4 ft wide. Now drifting north, and upraising on the vein, which continues to show the same character of high-grade ore at every point. A number of other prospects in the district are looking well. From some of these claims pay ore is being taken in good quantities. There are 25 to 30 men at work in the district. The mineral belt is about 3 miles long.

LEWIS DISTRICT.

MINING NOTES.—Lander *Free Press*, Oct. 14: The mines are all looking well and a large amount of work is being done. Managers and owners are putting forth their best efforts to crowd the work of development forward. Work in the Starr Orove mine is progressing finely. The lower south drift was extended 57 ft during the month, the upper south 60 ft and the incline shaft sunk 35 ft. Lower levels are yielding the usual amount of good ore which is being reduced at the Eagle and Starr Grove mills. Drift to connect the incline shaft with lower levels has been extended 40 ft and is in good ore. A frame building has been erected over the new boiler, and everything put in shape for winter months. Cloride is looking well and considerable ore being taken out. In the middle tunnel a good body of ore was struck last week. The winze progresses finely and the upper and lower tunnels have been extended rapidly. Eagle—During last month new shaft was sunk 35 ft. Both drifts looking well, and work being vigorously pushed. Highland Chief hoisting works have been completed and are ready to start up, being temporarily delayed for want of a new pump, soon to be supplied. Betty O'Neal—Stoping from lower levels, and hoisting ore that will average $200 to the ton. A new hoiler house has been built and the new boiler is on the ground ready to be set up. The pump and all necessary connections are also on hand, and as soon as the masons can be had the work will be pushed to completion.

MILL BUILDING.—Work on the new 40-stamp mill is going ahead as usual. The boilers, engine, pans and settlers are all set and the stamps are hung up. All that remains to be done is finishing up and putting on the belts. Three or 4 weeks will complete the work. A contract has been let for the building of another 40-stamp mill in Lewis. This time it is the Eagle Co. and the contractors are the same as those putting up the new 40-stamp mill under the agency of J. F. Courter. The site has been located just northeast of the Eagle mill. Work will not probably be commenced on the new structure until spring.

PIOCHE DISTRICT.

DAY CO.—*Herald*, Oct. 15: Following is a synopsis of the official letters of A. S. Gould, superintendent, under dates the 4th and 6th inst.: "Our general outlook continues good as ever. Day—400 level, south drift, advanced 5 ft; total length 55 ft. The entire face in excellent ore; 540 level sunk 4 ft north winze; total depth winze, 52 ft; bottom in spar and lime; 620 level driven 14 ft; total length 24 ft; upper portion of face in good vein matter; station cut out and still sinking—open country—fissures and seams. Ore house full and teams hauling daily. Mendha.—No material change. About 40 tons ore on the dump; sinking main incline in decomposed lime; have changed course of winze below 84 level, to westward. Will now follow the ore down from top of crossing. The stopes east 70 level are holding out very well indeed. Furnace—Doing splendidly; full supply of ores on dump; bullion product, $272 per ton, 4th inst.; abundance charcoal; machinery in best of order.

SEAMPEDE GAP.—Mines here mostly all doing well and promise to develop into valuable properties. Tom Brown brought in a number of samples from Simpson's prospect during the week from which assays as high as $500 were obtained. The men there engaged in getting out iron ore for the Bullionville Smelting Co. are doing well and have a number of fine ledges. There is a large force of men engaged in prospecting and working at this place.

PUEBLO DISTRICT.

COPPER MINES.—*Silver State*, Oct. 15: J. C. Wear, who owns several copper mines in the Pueblo mountains, northwestern corner of the State of Nevada, is in town. He commenced work on his mines with 4 or 5 men some 3 or 4 weeks ago, and has developed sufficient ore since then to warrant his company in erecting smelting works. There is plenty of wood and water in the vicinity of the mines, and the ore is of a quality that can be easily smelted in a water jacket furnace.

ANTIMONY MINES.—Messrs. Emmous & Jones, of Lovelock, have an antimony mine about 24 miles east of that station, on the eastern slope of the lower Humboldt range. There is said to be large quantities of the ore in sight, and San Francisco men have been examining it, with a view of purchasing the property.

SOLD.—John Robbins has sold the Buckeye and Hawkeye mines in Winnemucca mountain, to New York parties. The purchasers intend to develop the mines at once, and erect works to reduce the ores. Both mines have produced exceedingly rich ores, and are undoubtedly valuable property.

SAFFORD DISTRICT.

THE cold snap of the past few days has driven nearly all the prospectors away from the mines, there being no accommodations to keep them comfortable. An expert, in the interest of George Hearst and Haggin & Tevis, has been examining the Onondaga, and left the district last night for San Francisco, carrying with him ore from various parts of the mine. He expressed himself very well pleased with the appearance of the property, which now has a 50-foot tunnel on the ledge, and cross cuts that show up finely. The Contention mine, owned by the railroad boys, has a shaft of 20 ft, and the ledge is said to appear very bold. The first lumber for the camp arrived last Sunday, and a cabin has since been erected at the mines.

ARIZONA.

TOMBSTONE DISTRICT- ORANO CENTRAL.—*Epitaph*, Oct. 16: Sinking has been resumed on old shaft now down over 500 ft—new down 370 ft. Drifts and cross cuts being run actively. The stopes throughout the mine are all looking well, and the usual amount of ore is daily shipped.

GOODENOUGH.—The large ore body recently uncovered here, extending from the 200 level to the surface, will be thoroughly opened. Shaft No. 2, on the West Side, is down 127 ft, the drifts from the same making good progress. A shaft No. 1 the drifts are being driven ahead as rapidly as possible. The usual amount of ore is shipped daily. Machinery at the mill and mine is working satisfactorily.

CONTENTION.—Throughout this mine the work of development is being pushed ahead with the usual vigor, most of the labor, however, being carried below the 200 level. This company have paid their monthly dividend of $75,000; making for this year $675,000 paid to the shareholders.

VIZINA CON.—The depth of the shaft is about 425 ft, the bottom being in favorable looking vein matter yielding small assays, and nothing is more probable than that ore may be soon met with. The shipment of ore has been reduced to about 500 tons a month, which averages fully $100 per ton, the run of 612 tons last month returning $70,000, or a fraction over $114 per ton. The returns from 500 tons will pay all expenses and leave a handsome surplus for the future.

HEAD CENTER.—Most of the work performed here is above the 400 level, on the north end, the injunction of the Contention stopping all work in the southern portion. An upraise has been made from the 100 level to the surface, following the east vein. This was run for the purpose of demonstrating that the vein mentioned has its croppings within the boundaries of the mine. The stopes and winzes are looking well, and about 37 tons of ore are shipped to mill daily.

PROMPTER.—Incline shaft down about 200 ft, the ledge having increased considerably and improved in quality. In a short time crosscuts will be run and the ore body fully opened up, when a better estimate may be made of its value. Suitable machinery will soon be erected.

PENN.—Incline shaft down about 115 ft, showing considerable improvement in the quality of the ore. Altogether the indications are much better.

RUEY.—Vertical shaft down about 112 ft. Some very good ore is being extracted, but in small quantities. No crosscuts have yet been started.

TRANQUILITY.—Started up last evening. It is expected the Contentment will soon follow.

GLOBE COPPER.—The Carrie Copper Mining Co's. smelter at Globe started up on the 27th of Sept., and except for a few hours' delay on account of their pumps, has been running successfully since. They turn out an average of 1,000 lbs of copper every 2 hours, more or less, according to the grade of ore they are handling. The furnace is run with 3 shifts of men, and the company intend to keep it running right along, which they will have no difficulty in doing as there are ample reserves of good ore in sight at their mines.

COLORADO.

ABOUT LEADVILLE.—*Index*, Oct. 14: The reports of the smelters show about 35,000 tons of ore stored in the ore bins and piled up on the premises of the various smelters and mills. The producers are wondering where all the ore came from, while the smelting men all appear independent, and talk indifferent when asked to bid on ore, unless of a most desirable character. The amount on hand is more than equal to an entire month's output. The difficulty with water in the face of the Belden incline has been increasing, and steps are being taken to obviate the trouble. The water pipe for the State Line mines are expected to arrive at their destination by October 20th. The Battle Mountain Smelting company has begun the erection of the frame for the building of its new reduction works. The structure will be 80 feet square and enclose 2 furnaces, with an aggregate capacity of about 80 tons in 24 hours.

TEN MILE DISTRICT.—The Delaware mine is reported to have been sold at a high figure. The Ida L. mine is improving rapidly, and yielding fine galena and copper ore. The Greer smelter at Kokomo is in blast, and making bids for the ore of that district. Work has been resumed on the Blind Secret, Black Bess, St Elmo and Sabbath Rest properties. The Champlain tunnel on Gold hill, now in 400 feet, is to be pushed onward until mineral is struck. The tunnel on the Willie Warner, on Jack mountain, is in nearly 100 ft, and is showing up encouraging results. The Milo mine on Elk mountain, adjoining the Aftermath, is shipping 30 to 40 tons of ore per day. The mine is looking well. Work has been suspended on the Dauntless shaft of the Vermont and Colorado Mining company at a depth of 85 ft. The commodious shaft and ore house at the Michigan mine has been completed, and the new plant is in fine running order. The mine employs about 18 men. The recent discovery of carbonates in the Eagle and Raven mines, on Elk, is thought to insure the future of the properties and place them on a large and steady-producing basis. A shaft 5x14 ft in the clear is being sunk on the Cleveland, one of the claims on the Frentis group on Elk mountain. In addition to the strike in the Champion tunnel, another important discovery has been made in the little Minnie lode, on Sheep mountain, near the Wheel of Fortune.

DAKOTA.

RAILROAD.—The material for the Homestake railroad is coming in rapidly. Ten miles is already down, and in a short time the entire line will be in operation. This company has been the mainstay of the country; they have built the largest mills on the continent; given employment to a large number of men, who, but for their works, would have had no work; developed the mines and have proven in spite of the croakers and testimony of so-called experts, that our leads are genuine and permanent.

IDAHO.

WOOD RIVER COUNTRY—YANKEE FORK.—*Herald*, Oct. 15: Locations are still being made on the Liberty, on Squaw creek, and they all show up finely. Quite a number of prospectors are digging up the country, and a good many more finds will no doubt be recorded before winter. If depth reveals as rich and extensive ore bodies as have been exposed at the surface, a smelter will be put up next year. The ore is rich in copper, to say nothing of the silver. The Garfield, on Henry creek, is being developed by Ralph Goodliffe and the Bayhouse Brothers. S. K. Goldtrap has put 4 men to work on the Liberty mine, on Squaw creek. The Elmira company is putting in a steam pump to raise water out of the lower level of the Crown Point. The water will be conveyed through the lower and main tunnel, 35 ft below which work is now being carried on. A 3-ft seam of bluish colored ore was struck the other day in the drift running west from the 75-ft level in the Sub Rosa. It is the same character of ore that was mined several years ago near the surface, 000 tons of which milled between $25 and $30 per ton. The ore of this last strike will turn out about $20 per ton. Thirty tons of ore are on the dump of the Sub Rosa. A force of ten men are at work in the Ebenezer. Sixty tons of ore are on the dump, and as soon as 40 more are extracted it will be crushed in the Gold Hill mill. The lower tunnel of the Sub Rosa is in 375 ft, and it is expected the vein will be tapped by it soon. John and Fred Frank are taking out a crushing of ore from the Tidal Wave, which will be reduced in the Sub Rosa mill.

SAW TOOTH CITY is quite lively, and a number of new buildings are in course of erection. Seventy-five men are employed at the Columbia and Beaver mill. A new mill has been ordered for Smiley gulch.

MONTANA.

BUTTE DISTRICT—ALICE MINE.—*Inter-Mountain*, Oct. 14: On all the levels extraction of ore is proceeding as usual, and on the 2d, 3d, and 7th the drifts are being forwarded. The quality of the ore throughout the mine is good enough to insure handsome profits, and the amount so large that sinking for the 800 level will not be started for some time.

MOULTON.—Seven hundred tons of ore on the dump, sufficient to last the mill three weeks. Explorations are progressing vigorously, and every part of the mine looking wonderfully well.

BELL.—Appearance of ore unchanged, a profusion of native and wire silver visible on almost every piece extracted. The percentage of copper remains at from 40 to 60. Smelter rapidly approaching completion.

LEXINGTON.—No important developments the past week. Until the 200-ft north crosscut taps the main vein operations in the old workings will not be resumed on account of water. The main shaft, of 240 ft. deep, and sinking progressing.

ITEMS.—Two carloads of matte from Butte arrived in Ogden on Thursday. The erection of the Bruckner cylinder began in the Alice mill this morning. Bullion shipments from Butte for the week ending Oct. 15th, aggregate $57,870 20. The strike of the Colusa holds out in good shape, the silver value of the ore being much higher than was expected. The shaft of the Butte Original has reached a depth of 200 ft and stations are now being cut for the 100 and 200 ft south crosscut.

NEW MEXICO.

MOGOLLONS.—*New Southwest*, Oct 15: On the Silver Bar work is being pushed rapidly. Capt. McAllister, one of the pioneers of the camp, has taken a contract to run the lower tunnel 80 ft farther, so as to strike the junction of the upper and lower leads at a depth of 500 ft. A 20 ft shaft is being sunk on the new lead 80 ft from the point of connection with the old lead. The mineral increases in value as the work goes on. The character of the ore on the new lead which is 4 ft wide is mostly gold, but also a large percentage of silver. It has been found, discovered by assay, that about 10,000 tons of surface rock hitherto considered valueless, are rich in both gold and silver free milling ore.

PLACER MINING.—A large number of men are making good wages at placer mining a few miles from Silver City, in different gulches. Should the rains continue this will remain one of the paying industries of this section of Graut county for some time to come.

OREGON.

QUARTZ DISCOVERED.—*Dalles Times*, Oct 15. Quartz lodes of apparent value have lately been found in the Eagle Creek mountains, in Union and Baker counties, about 35 miles east of Union. The St. Elmo runs from $12 to $200 to the ton in gold and silver; the Badger will "mill" from $6 to $31 to the ton. These are well defined ledges and easy of access. The "Badger" is close to the surface, and can be distinctly traced for a long distance. The St. Elmo can be readily seen cropping out for a distance of 9,000 ft. About 20 miles distant from these quartz ledges, across Snake river, in Idaho, is a bit of country rich in galena, copper and iron, and the former metals have mixed with them large quantities of gold and silver. The iron is contained in a solid mountain, all of which will assay about 80% of that metal. This country is situated directly on the proposed line of railroad down Snake river, which, if built, will furnish a means of shipment for these valuable ores.

UTAH.

PARK CITY.—Salt Lake *Tribune*, Oct. 17: The Pinyon is shipping about 15 tons of ore per day to the Salt Lake smelters. A strike may be looked for in the Utah before long. The crosscut is now nearing the vein. Recent development in the different mines on Pinyon hill are showing up large bodies of ore, and tunnels, shafts, or drifts, in whatever direction run, cut right into it.

SILVER REEF.—*Miner*, Oct. 8: So far as we can learn, there is nothing in the mines but prosperity to note. The promising condition of the different properties is shown clearly in the impetus given to all branches of business, and the qualities of merchandise and mining supplies being received daily by the merchants and companies is far exceeding any previous average. The Stormont Co. makes a deserving record, and from the official reports we condense the following: Total bullion shipment from July 6th (the date of resumption at the mill) to Sept. 30th inclusive, $93,821.68—or an average of about $32,000 per month. The surplus of this amount over and above expenses and dividends has been largely used by the management in prospecting the property and placing the mine in its present productive condition. The ore bodies now uncovered and yielding treasure are estimated of sufficient scope to furnish product for at least 6 months' run of their stamps. No less than 3,000 ft of direct levels and winzes have been driven since the date of resumption. The Barbee & Walker can also make an exhibit that speaks well for the merits of its mine and mill capacity, and management. We find the official figures to show the following gratifying result: Total bullion product from July 17th (date of mill resume) to Sept. 30th, $72,958.21, which makes a grand average for the actual running time of 66 days (deducting 9 days stoppage for repairs to engine) of $1,105.42 per day, or $33,192.60 per month.

Sulphur in Ores.

At the meeting of the Polytechnic Association of the American Institnte, on Septemhsr 15th, Mr. N. S. Keitb, opening the regular subject of tbe evening, explained the difference hetween volatilizetion and burning of the enlphur in ores. There are two atome of sulphur in the sulphurets, one of which ie more easily parted with than the other. A moderate beating drives out one, and it is expelled simply es eulphur, and can he recovered as such. The otber can only be expelled hy a combination with oxygen, in common language hurning, forming eulphurous acid. His experience had heen entirely with tbe ores of tbe precious metals; he bed worked on a large scale end invented improvments, which be described. He had committed the same error in part tbat many others bad of attempting to cerry tbe saving too far. It wae economy to go to great extent in utilizing the waste from silver processes, hecauso the combinations assumed hy silver would otherwise carry off a large proportion, nearly tbe whole, but it was not so with gold.

One of tbe favorite ways to burn the sulpbur from ores wes to pulverize, or rather to crush, finely and sbower it down through a flame of wood or coal. The eulpbur would add to the fuel so tbat little more was required witb some ores. The draugbt would cause some of the finest to blow away. He had arranged eettling chambers, extending a long dietance, to recover tbat dnst; it did not pay.

Mr. D'Heureuse drew end explained a desulpburizing apparatus recently constructed, and now working on a large scale in Brooklyn, a modification of the Stetevelt first described. Instead of using wood or coal these parties used petroleum as tbe fusl to keep up the flame in the tall cbamher. Instead of showering in tbe fine ore hy pessing through rollers it was in thie apparatus passed in with a blast of air.

Mr. D'Heureuse had examined cbemically and microscopically, after thoroughly braying in a mortar, the dust whicb bad passed through this treatment, and found no remaining sulphur. He attacbed importance to the absence of any coating around the particles, which was liable to be found when the ore was hurned witb fuel producing ash.

Artesian Wells in the Black Hills.—Yankton, crippled in business and suffering from a leck of good water, resolved to supply the want by an artesian well. The city contributed liherally, and the result is, their labors bave been crowned with success. To-day they bave an ample supply of tho indispensable fluid. Tbe great trouble in the Hills has been the want of water for mining purposes. Almost daily mills have to hang up tbeir stamps from lack of water. Tbis is a severe loss all around. But a few days ago the tanks of the city were nearly dry. This was caused, it is true, by tbe waste of our citizens; but to replenisb our etock the mills had to shut down, to their loss. Ae a country the Hills ere amply supplied witb water, but for the purposes of mining it is hadly distributed. Many of our great mines, hotb lead and placer, are upon the crests of mountains above the fountains of our streams, or where they are but insignificant rills; the greatest economy has to be exercised in its use. So far as our city and the great mills are concerned we have at the present moment ae mucb es we probably will have from remote sources. All tbe water which can be brougbt in we already have. If mills and menufactories multiply, as tbe demende of the country indicate they will, tbe water supply becomes a serious question. As time passes this want will hecome more pressing. The Hille are being rapidly denuded of timher. As a natural consequence there is less rain. We will at last have to rely upon artesian wells. One sucb equal to tbat at Yankton would amply eupply our mills and perhaps the surrounding cities. The cost of euch a work, driven ae it would have to be tbrough solid rock, would be great, but the result would repay tbe outlay.—*Black Hills Times.*

No Invasion of Possession.—Tbe Supreme Court has rendered a decision wbicb affirms the doctrine that, by Congressional Acts, exprees reservation was made of tbe rights of mining and irrigation ditches in sales of public lands. W. H. Farley had brought suit against the Spring Valley Mining and Irrigation Company in the late District Court of Butte county, to recover damagee for injury to hie 80 acres of land, caneed by their flooding from the company's reservoir. Upon the trial of the caee the plaintiff sbowed tbat be had proved up and paid for the land, claiming that it was part of the public domain even after the company had built and filled its reservoir, which was previoue to hie purchase. A nonsuit was granted, wbicb decision tbe Supreme Court yesterday affirmed, bolding tbat until Farley had "proved up" and paid for the 80 acres, in 1877, Congress bad full power to withdraw the land from sale or to eell it or grant it to another. The Supreme Court holds, furthermore, that the effect of the Act of Congress of July 26, 1866, and of July, 1870, amendatory thereof, is to grant to the company the rigbt to conetruct and uee tbe reservoir and other rights reserved in the patent issued to the plaintiff euhsequently. He was not entitled to judgment, for in the conetruction of the reservoir the company did not injure or damage or in any way invade tbe possession of tbe plaintiff.

A Great Mine.

Thougb we live in what might be termed an exclnsively mining region, yet few of us stop to think relative to the details of expanse necessary to the sucesssful working of e great mine. It is our purpoee to give a few figures in regard to the Tombstone Mill and Mining Company, hotb as to outlay and returns, wbich will doubtless interest the mining public.

This company handle every month 23,000 tons of ore; to convey this ore from the mine to the mill, nine miles distant, it requires six teams, each team hauled by sixteen mules. Each team makes a round trip between tbe mine and tbe mill every day. This company bave in operation tbree hoisting works with an average capacity of 200 tone per day. Tbey bave two mills, one of 20 stamps and one of 15 stamps. Tbe latter (15 etamps) can he run hoth by eteam and water power. At tbe mills and mines of this company 250 men are employed, who receive an average of $4 per day, making the outlay for labor alone, eacb day, $1,000. The average shipment of bullion per month bas been $120,000 for the eix months last past. Tbe ore is boisted hy power and carried on tramways to ore bins, which are so constructed that ore teams are driven immediately underneatb the hins, and a trap door opened through which the ore passes to the wagon-bed beneath. At eacb of these bins are assorting floors, where the ore is carefully separated from tbe waste. Tbe eurface ground of thie company's mines covers an area of 169 acres. The Tombstone Mill and Mining Company have disbursed, since operations commenced in 1879, tbe sum of $850,000 in dividends, bsing one out of only twenty-five mines, in the bistory of mining in tbe United States, wbicb has dishursed that amount. The first bullion was produced in October, 1879. It was tbe first mine opened in Tombstone District—huilt tbe first mill, milled the first ore, produced tbe first dividend and has continually paid dividends from that time to this.

The bullion ie shipped to San Francisco and sold to the United States Mint. A branch mint sbould be established in Arizona. The number of hnllion-producing mines now in operation within the limits of tbe Territory, together with those which will within the coming year he bullion producers, must force upon the Federal Government our claims for a mint. The effort to create a market here for the purchese of Mexican coin, to re-mint it, is in direct opposition to the interests of bullion-producing mines in Arizona, as it would he bringing foreign bullion in competition with our home product. We trust our delegate to Congress will not forget a hranch mint for Arizona. Trnsting our readers will excuse this diversion, relative to a branch mint, we return to the Tombstoue Mill and Miniug Company, and propose to say a few words in regard to the operation of mines by Eastern capital, it baving heen tbe bahit of many in our Territory to criticise eeverely Eastern capitalists and their mauagement of mines. These minee have heen worked by Eastern capital exclusively, from first to last, requiring the ontlay of large sums of money, but they have been successfully operated, and we venture the assertion that when the property is good, Eastern capital will not he lacking to develop and forward it to a dividend-paying mine. The operations of this mining compauy are carried on by Prof. John A. Church, Superintendent; James Kirk, Foreman in mines; S. W. Wood, Manager at the mills; D. McCarty, Assayer.—*Arizona Journal.*

The Belmont Mining Company's New Furnace.—Tbe Belmont mining compeny has purchesed a new roaster called the Pacific Improved Chloridizing Furnace. This is a new style of charging furnace—an improvement on what is commonly known ae the Bruckner Cylinder. For gold eulpburets or very hase silver oree it is regarded hy many as the most eimple and moet effective furnace in uee. The ore is at all timee under perfect control, and the charges can be run any length of time until in proper condition to be drawn, tbue making it peculiarly adapted to all classes and conditione of base ores. The hoppers hold a full charge, and only five minutes are required for charging tbe cylinder. To discharge it, tho cylinder ie run about thirty minutes with the doors open. The amount of ore they will handle per day of course depends upon the length of time required for eacb charge, whicb averages all the way from five to fifteen hours. Four of tbem bave heen in operation at the White & Shiloh mine in Nevada for the past two yeare, working witb great economy and eatisfaction, the hasest oree in this State, up to an average of over 90 per cent. After a long series of experimente the mecbanical conetruction has been brought to such a degree of perfection tbat no lose or annoyance is experienced in the way of etoppage for repaire.—*Belmont Courier.*

A New Motor.—A German paper describes a new motor which is eaid to he driven by a new force more powerful thau eteam, which has the additional adavantage that it can be generated in ahout hve minutes, without the aid of fire or water, to attain a preesure of 10 atmoepberee without emitting any noxious vapors. The particular machine is rated at 2 boree-power, while occupying a epace of hut 11⅔ cu. ft., and weighs, with tbe motive power, but 330 lbs. We sbonld be glad to eee it.

The New Mines on the Mojave.

How to Get There, and all About Them

The newly discovered mining region on the east of us, in tbe county of San Bernardino, is at tbis time attracting a great deal of attention, not only from the citizens of these two counties, hut from mining men and opsrators elsewhere, who make it a business to look after and examine into all the newest and latest discoveries. For the purpose of getting, as far as possihle, an intelligent description of the situation of tbese districts and the mode of getting to them, we present the following particulars just gatbered by one of our reporters just returned from a tour of observation in that region:

The Oro Grando district is eituated on the Mojave river, about 80 miles from this city, or about 40 milee from the towu of San Bernardino. From the town of Oro Grande, tbe road leads down the Mojave river ahout 30 miles to Grapevine etation, situated on tbe north hank of the Mojave river, where there is a trading-post and where accommodations can be had for man and animals. Tbie is in the Grapevine mining district, and immediately north of the station, about three miles distent, is eituated tbe now celebrated Waterman mine, together witb many other later locations, which have not, as yet, been prospected sufficiently to prove their value or importance. The Waterman company is building a 10-stamp mill, and other improvemeuts on the river ahove, about one mile, where there will be a store, boarding-honse, etc. East of Grapevine etation, abont six miles, on the Mojave river, is Fish Pond station, long used as a stopping place on the Fort Mojave and Ivanpah road. Ahout ssven miles northeast of Fish Pond etation is eituated the Calico mountain, upon which the Silver King, Burning Moscow and Oriental claims are located, on the soutbeasterly portion of the same; the Burning Moscow being considered the nortbwestern end the Oriental the southwestern continuation of the King lode. Calico mountain is a low mountain not of any great extent, and several locations round and about tbe portion discovered, and on the nortbern portions of the mountain, are considered by the locators to be of great promise; but it will require labor and capital to develop their intrinsic value. Ahout one and a half miles from the Silver King mine, on what is known as the Dry Lake, on the road leading from Fisb Pond to Calico mountain, a well bas been sunk, and at tbe depth of 80 ft. an ahundant supply of water is obtained.

The different mining camps in and about there are being supplied therefrom. Ahout midway between the hill or mountain on which the Waterman mine is located, and Calico mountain, ie a low hill known as "Black mountain," upon which some very promising locations have heen made. Notices and monuments ars plentiful everywhere, and the number of locatioue made in all parts of the district are innumerable, it appearing that parties have located everything that bas any appearance or resemblance of a ledge, for the purpose of taking tbe chances, without any desire or idea of doing auy work upon their locations, but waiting to see what the futnre may bring forth. It is hard to estimate the number of men at work or prospecting in the district as they are scattered here, there and everywhere, hut the aggregate number is larger than one not acquainted here would suppose. Prospecting parties are branching out in all directions, north, eoutb, east and west, prospecting in every range tbat can he reached. But this mode of prospecting is limited to tbose wbo have teams to haul water, as that necessary article is exceedingly scarce in that region, except in tbe immediate vicinity of the river. Several promising new diecoveries are already reported, and now that tbe summer season is over otbers may he looked for at any time, as it now appears that each and every range of mountains conteins ledges of greater or less richness or extent. To the east of Calico mountain about 120 milee distant and ahout 20 miles eouth of the road leading to Fort Morgan, ie situated tbe Trojan district, in Providence mountain, where Gillette & Co. bave lately purchased the mines loceted hy McFarlane, Osborne and others, for $300,000. Many loaded teame were met on the road with freight for the last named district, whicb sbowe that active operations are now going on in that direction. In short, there is great activity in mining matters through that entire region, and there is no douht of the richnese of the surface prospects. Much of the rock ie fahulouely rich, and if it continuee to hold out—if it poseesees permanence—if there is only enough of it—it will certainly prove one of the leading mining regions of the Pacific coast and add greatly to the wealtb and business reeources of southern California.—*Los Angeles Herald.*

Russian Mineral Statistics.—The Rneeian report on mineral etatistics for 1879, whicb hae juet been publiehed, givee tbe yield of gold in Russia for that year at 42.5 tone; eilver, 11.2 tons; platinum, 2.2 tons; zinc, 4,250 tons; copper, 3,074 tons; lead, 1,335 tons; pig iron, 479,865 tons; coal, 2,872,367 tons; crude petrolenm, 346,274 tone.

The Gold Supply.—Tbe supply of gold in tbe United States hae been increased to the amount of $175,000,000 during tbe last two years, exclusive of the home prodnction. This great drain of the precious metals from Europe is the cause of the late advance in interest, in all tho money markets of that contiuent.

Demand for Quartz.—It seems that tbere is a scarcity of gold quartz in San Francisco, and the manufacturere of quartz jswelry cannot supply the demand, owing to lack of material. Through the kindness of Mr. A. Howard, the leading jeweler in this city, we are permitted to take extracts from a letter received hy him from one of the largest manufacturing firms on this coast. The firm says: "We notice in the *Mercury* that fine specimens of gold quartz are heing brought into your city from mines near by. Gold quartz is getting very scarce now, in thie city, and we have tried Nevada City and Grass Valley, and are unable to ohtain any. If you can send us some quartz for cutting, we will pay from $20 to $25 per ounce for the gold tbat is in it. Should you be able to get eome nice black quartz, we will pay $30 per ounce. In sending pieces from different partiss you can number them, and we will let you know how much they are worth, and if the parties are not satisfied we will pay expressage hotb ways. Any colored quartz will do—white, gray, or black; the only thiug required is that gold must be seen from tbe outside. You have no idea how mucb we want quartz. I bave written more than 10 letters to Nevada City, and only got a small piece. I wonder if you will be able to do anything toward getting me some." Here is a chance for some of our quartz men to make some money. Hardly a week passes that our attention is not called to a fine specimen full of free gold. Only last week a miner struck it rich, and gave away to bis many friends at least two dozen specimens of just the kind of quartz that these gentlemen are willing to pay $25 an ounce for. Of course there are not many claims that show up free gold in any great quantity, hut still, pockets are being struck, and beautiful specimens taken out.—*Oroville Mercury.*

River Mining.—Old and experienced miners, says the Yreka *Journal*, consider that the hest way to make river mining successful is to prospect by sinking a sheft as in quartz and placer mining, using a good pump run hy river power to keep the water out while going down. This metbod would certainly make a suro thing on securing good pay for tbe erection of extensive machinery and apparatus, if good prospects are obtained. Tho extent of richness of the bedrock gravel, and the deptb to go down from tbe surface, could allow easy figuring as to the probahle succese in drifting or making an open cut. It is believed that many of the river claims would pay hetter by drifting, in plece of so much dead work to uucover the eurface or non-paying top dirt, especially where 40 or 50 ft. must be removed with the hardeet kind of labor and scientific skill, and so many huge bowldere exist. Besides, the work of drifting might be prosecuted all the year round, if the drifts are run in a secure and substantial manner by extensive and thorough timhering. In the present method of wingdamming and making open cuts, the same work has to he renewed every season, leaving but a very short time for hedrock cleaning hetween the time tbey reach bedrock and the commencement of the winter with heavy rains to flood them out.

New Gold Separator.—The Ferndele *Enterprise*, Humboldt county, dcscribes the following gold separator, an invention of that vicinity, in the language of the inventor: "I conetruct a round cone, the point uppsrmost, the side of the cone sloping to snch an angle as to give the sand and water the proper velocity. Through a common sluice-box I cause sand and water to flow on to the top or point of the oone; here it ie spread and diffused by the constantly increasing size of cone downwards, until at the lower part of the cone it will he a mere film of separate grains of saud. Tbe lower part of the cone will be covered by quicksilver plates, and there will be quicksilver in suitable riffles. The sand containing the gold can, by this means, he forced, every particle of it to come in actual contact with tbs quicksilver, and the gold, where not coated hy rust or by some oily substance, must adhere and form an amalgam."

A Wagon that Carried 4,500 Tons of Gold.—The little old "gold wagon" in New York that carried gold from the Custom Honse to the Snb Treasury has heen put aside. Sometimes it made as many as a dozen tripe daily, carrying as much as $80,000 in glittering gold coin each time. The money ie usually put up in bage of $20,000 cach, whicb are placed in heavy oaken boxes witb maseive rod iron handles. These hoxee are then put into the wagon-box, and a lid witb clainps of iron ie locked down over it. The wagon is pushed like a hand-cart hy two Cuetom House porters, accompanied by an armed watchman, whoee duty it is to see tbat tbe load ie not interfered with hy thieves. The little ueed-up wagon has carried in its time prohably not lese than $500,000,000, or abont 4,500 tons weight in gold.

Two "ecientiete" of Colorado are quarreling about the priority of the invention for the extraction of the precious metals from qnartz without mining it. They melt out the metale hy melting down the monntaine; or at least claim to he ahle so to do, having met witb "snccess on a emall ecale." Probably hy melting molehills.

Simplyfying the Steam Engine.—A French patent ie to make tbe engine with the feweet numher of parts. The cylinder and piston are hoth made of only two pieces holted together in the middle, the crank-pin works in a hlock which elides hackward and forward in a slot, and the valve ie driven from the emall crank.

Stealing Specimens.

The Nevada *Transcript* says: Most mining companies whose ledges contain what is known as "specimen ore" sustain heavy losses through the tricks of dishonest employes. Numerous cases are reported here in Nevada county where miners working for $3 a day, and supporting large families, have accumulated wealth with such remarkable rapidity that in a very few years they have been enabled to retire from the field of active labor and live on the fat of the land, and this when it was positively known they had not been dealing in stocks.

The "tricks of the trade" are numerous, and in view of recent happenings it may not be amiss to describe some that are connected with the history of gold mining in this locality.

One trusted employe of a well known company that frequently developed "pockets" in the course of its operations had a practice of lighting his tobacco pipe every time he was coming off shift, and enjoying a smoke as he rode to the surface and walked homeward. The pipe had a bowl that held almost a handful of tobacco, but despite this extravagance the man, in addition to having a snug bank account, lived in good style, dressed his family nicely and gave his children quite an expensive education. How he could do so much on $3 a day was a mystery for several years. Finally, one morning, as he stepped into the dry-room after ascending to the surface, the bowl of his pipe separated from the stem and fell to the floor. The Superintendent of the mine happened to be there, and it rolled to his feet. He courteously stooped to recover it for the owner. As he did so he observed it was very heavy, and turned it over in his hand with curiosity. The miner saw the motion and got nervous. The Superintendent noticed the peculiar action of the miner, and a ray of suspicion entered his not over-astute mind. He walked out of the room with the pipe, leaving the miner in a greatly excited condition. When he got to his office he made an examination. In the bowl he found a rich specimen covered by a thin layer of tobacco. The smoker never worked in that mine again.

A miner who had always enjoyed a spotless reputation for being upright and industrious, went to a Grass Valley physician some years ago to be treated for what the patient claimed was "blind piles." An examination of the case showed that the patient's only chance for recovery was to submit to a surgical operation. The operation was performed, and a ragged chunk of gold was found in the anus. The man died, thus paying the penalty of his dishonesty.

Another instance was where a miner, who was regarded as eccentric because he let his hair grow nearly to his shoulders, used shoemaker's wax to fasten specimens close to the roots of the hirsute covering, and he is supposed to have carried on the robberies for some years before being detected.

Another was the object of frequent jests because of the size of his nose in the vicinity of its bridge. The nostrils were contracted at the outlet, and expanded as they went upwards. It was not until some one finally detected him in smuggling nuggets out of the mine by putting them in his nostrils that the advantage of such a nose was appreciated by his fellow-workmen.

A dentist in this city had a call from a miner who was suffering with the toothache. While examining the offending ivory, which was a hollow one, he prized out a small piece of quartz heavily charged with gold. He accepted it as pay for his work and considered himself well remunerated. It is probably unnecessary to add that the quartz was not put there by a dentist.

There are other dodges daily resorted to by specimen thieves. The cases we have referred to are those of quartz miners. Some day we will tell how the owners of gravel claims are robbed.

Vest Pocket Assays.—How strange it is for miners to salt their mines on themselves! Miners will open their prospect holes, put a piece of rock in their pocket as big as a walnut, get a big assay, then show it around, telling everybody they have from two to four feet of such material—tell it until they appear to believe it themselves. But when they finally conclude to get a mill-run, they shovel up their dump, get a run, and it goes, say, 20 ounces; they denounce the mill men. What nonsense! Now, miners, do you know that 50 ounces is above the average of milling ore in all mining countries, and that a pay streak of four inches is a good average vein? If you have only a little rich ore sort it carefully and take it to the nearest ore market. Men on the hunt for mining investments look around the smelters. A few sacks of fine ore in a smelter beat a heap of wind puffs. Suppose you have only a few hundred pounds; get up your jack, pack it over, get your money, he it ever so little; keep to work. One worked mine is worth a dozen idle prospects. You will never sell by standing idly by and blowing about your $50,000. Get in your ore; then you will have some good sales.—*Gothic Miner.*

People should avoid, as far as possible, being run over by railroad cars. An empty platform car weighs 18,000 lbs.; an empty box car, 20,000 lbs.; a passenger car, 36,000 lbs. and sometimes more; and an average locomotive, 80,000 lbs.; a single pair of car wheels, 500 lbs.

Useful Information.

A Peculiar Property of Gutta-percha.

It is a well-known fact that when gutta-percha is placed in water having a temperature of 60° to 70° C., it becomes very plastic, and may be used to receive very delicate impressions. Not so well known, however, is the information that the softened gutta-percha becomes very elastic toward severe shocks, that it will bear blows from large hammers, and allow itself to be thrown against a strong wall without showing any indication of the result, while at the same time it is so susceptible to gentle pressure that it is capable of receiving the slightest of impressions.

This peculiar property is possessed by other plastic bodies though in a less degree, as, for instance, freshly kneaded bread. It is considered as resulting in consequence of the occluded air contained in the substance.

The following simple experiment demonstrates the correctness of the above suggestion: Two spheres of equal weight are made of gutta-percha which has been softened in water at 70° between the palms of the hand. One of these is placed on a card, and the air removed from the sphere by exhausting it under the receiver of an air pump; the other is retained for comparison. Both spheres, from their weight, will assume the form of round cakes, but the one under the air pump will swell considerably and exhibit a wrinkled surface. The increase in volume often more than doubles its original size. If the swollen piece is permitted to harden under the receiver of the air pump and then broken with a chisel, its close section will appear honeycombed like the interior of a loaf of bread, while the fracture of the other pieces will only show small cavities. Very dense gutta-percha does not swell under the air pump, but if placed under mineral oil and made empty a voluminous evolution of air from the gutta-percha will take place.

After the air is again admitted under the receiver it will be found on examining the gutta-percha that it has lost the property of hardening on cooling. It has become like tough, greasy leather. A voluminous evolution of air was also observed when clay, putty and kneaded bread were examined under oil in vacuo similar to the above described treatment of gutta-percha.

The same phenomenon was observed when a sample of gutta-percha, which had been softened in an air bath, was treated as above; in this case a longer time is required for the heating, as the heated air is very slow in giving the amount of required heat.

With some bodies the enclosed air plays an important part in affecting their mechanical properties—thus clay, for instance, may be somewhat compressed by means of a piston in a cylinder; but as soon as the pressure ceases, it resumes its former volume.

The densest clay, when placed under the air pump, will become covered with numerous fine crevices (small as hair), which close up when the vacuum is sufficiently reduced.—*Dingler's Polytechnis.*

To Cover Wire with Gutta-percha.—The *Mechanical World* gives the following as an easy method for covering copper wire with gutta-percha for electrical purposes: Some commercial gutta-percha cut into small pieces is introduced in a bottle containing sulphide of carbon; this bottle must be well stopped. If agitated from time to time it dissolves at the ordinary temperature. When completely dissolved it is left to stand some days, until the impure matters deposit at the bottom. It is then poured into another bottle, which is also kept well stopped and at a low temperature; for thick wire the solution must be concentrated. The wire being dipped in this solution, the sulphide of carbon, evaporating, leaves on the surface a layer of gutta-percha more or less thick. In order to operate continuously, the solution is poured into a V tube, through which the wire is passed over a wooden pulley. The distance between the tube and the bobbin upon which the wire is rolled is about ten yards. In order that the sulphide of carbon may evaporate, this operation should be carried on in the open air.

Staining and Matching.—To stain mahogany a dark color, dissolve bichromate of potash in warm water, and apply it to the parts to be stained; it can be made weak by adding water, and the learner should use it weak at first, or he may make his work to dark; when dry, paper down. A little red sanders used in the polish makes it a bright red color and improves the staining; this stain is used in matching mahogany work that has been repaired. If the work is not required to be very dark, a little red sandera mixed in the polish will be sufficient. This is likewise used for birch or any wood that is used to imitate mahogany.

Oil on Woodwork. — Carefully conducted experiments have demonstrated the fact that seasoned wood, well saturated with oil when put together, will not shrink in the driest weather. Wheels have been known to run many years, even to wearing out the tires. Very many dollars might be saved annually if this practice were adopted. Boiled linseed oil is the best for general use, although it is now known that crude petroleum on even old wheels is of great benefit.—*Young Scientist.*

"Rough on Rats."

In every drug store in the land are seen placards bearing the inscription "Rough on Rats." Do the people know that this preparation thus advertised is just as rough on human beings? A chemical examination shows that it consists principally of *arsenious acid*, a deadly poison. Recently we have word from New Orleans of a whole family poisoned by this dangerous substance. Druggists in most States are prohibited from selling arsenic without plainly labeling it "*Poison*," and taking great care to keep it from the ignorant and careless, but here is *arsenic* sent into every house with no precaution whatever. Is there not need of some regulations in these matters? Arsenic sells at *wholesale* at from *one* to *two* cents a pound. Rough on Rats at 15 cents an ounce. Quite a fair percent of profit.

There is another form of arsenic sold in the drug stores with no warning. It is "cobalt" or fly poison. Cobalt is only a soluble form of arsenic, and being soluble, is really more dangerous than common arsenic. But do the people know this?

Paris green is still another deadly form of arsenic, in reality a compound of arsenic and copper, both of which are poisonous. In the fluids of the alimentary canal, Paris green readily dissolves and rapidly proves fatal.

Owing to its cheapness and the brilliant colored compounds which this drug forms, arsenic is used in great quantities in hundreds of places where it would never be suspected. It is found in wall paper, paints, calico, rubber nipples, confectionery, colored crayons, glass, glazing materials, etc. Strange as it may appear, arsenic is used in some countries as food.—*Science and Health.*

A Vast Lead Field.—The upper Mississippi lead fields include 2,000,000 acres—200,000 in Iowa, 400,000 in northern Illinois, and 1,400,000 in Wisconsin. The value of the gross amount of lead produced in that field since 1826, is about $70,000,000.

Compressed gunpowder experiments have been made with compressed gunpowder, made to fit the drill holes and cut into short lengths. It was found to possess many advantages over loose powder, among which is a saving of 40% in powder.

Good Health.

Concerning Mountain Cures.

There is one feature connected with mountain cures which should not be overlooked. There are, speaking broadly, two classes of persons to whom the mountains offer health. One class comprises those who have been overworked in the city, whose lungs, digestive organs, eyes, etc., are out of order, and want air and exercise. This class of persons, we may say at once, could get cured as well on a plain or on the sea as in the mountains, so long as they get air and exercise. But there is another class to whom the mountains offer special advantages. They are afflicted with a kind of phthisis which needs bracing, rare, stimulating, dry air. To go to Colorado, New Mexico or Arizona is new life to them. But cures of this character are conditional. A young man left Philadelphia for Minnesota some time ago in an almost hopeless condition, and in a short time his constitution was built up by the new air. The most biting cold of the Minnesota winter did not harm him. He wanted to exhibit his health to his Philadelphia friends, but a return to the City of Brotherly Love brought back all his old alarming symptoms. He had to flee to Minnesota again, where he once more found perfect health. Then he took a trip to the far West. But at San Francisco his old trouble returned. We repeat—the man who wants air and exercise and goes to the mountains, where he recuperates, is different from the man who needs air of a peculiar kind to aid him in warding off consumption. This latter, when he gets where he finds vitality in the air, must follow the advice Sumner gave to Stanton, in that expressive word "stick."—*Herald of Health.*

Death from Pricking a Sore.—Recently a young married lady of Albany died in the Adirondacks under circumstances of the most singular nature. Before going out driving she pricked with a brass pin a cold sore on her upper lip, and rubbed it with camphor. Before she reached her hotel her lip commenced to swell, and before night her face was swollen to an abnormal size. Her husband was telegraphed for and arrived before the unfortunate lady died, but she could not speak to him, such was the condition of her face. Erysipelas had set in of the most virulent type, and death resulted within 48 hours.

To Remove a Finger Ring.—Thread a needle with a strong thread; pass the head of the needle, with care, under the ring, and pull the thread through a few inches toward the hand; wrap the long end of the thread tightly around the finger, regularly all down to the nail, to reduce its size. Then lay hold of the short end of the thread and unwind it. The thread pressing against the ring will gradually remove it from the finger. This simple method will remove a very tight ring without difficulty.

Civilization and Health.

Is the human race deteriorating, physically? In other words, is civilization a shortener of life, or otherwise? Although much may be said for the haleness and heartiness of our grandfathers' and much against the pale, slim, city-bred dyspeptic, yet we cannot but come to the conclusion that the race is not in so sorry a plight as some people would judge.

Among savages life is short, and it is the exception for a man to attain to 50 years, while long before that his powers are decayed. Then, too, in the records of English courts, from the 13th to 16th century, Sir Thomas Hardy found no instance of a man who had survived his 80th year, and the age of 70 was rarely reached, and was regarded as extreme.

The advance in medical knowledge, the spread of education and sanitary improvements have, taken together, had a great effect in adding to the average of men's lives. It is true we see certain unwelcome signs of decay, notably in the teeth of the present generation; but these are the result of local causes which, it may be hoped, will disappear in course of time. Railroads and steamships do much, indirectly, to benefit the race constitutionally, in bringing together to this country hardy representatives of other races. The intermixture of blood which is the result cannot but exert a highly beneficial result on this nation. In this matter we are, as a people, highly favored, and the time may be looked for when Americans will stand out before the world, more even than now, as one of the healthiest nations extant.—*Herald of Health.*

An Anti-Vaccinator's Fate.—Possibly the bitterest opponent of vaccination may be impressed by the grim details of the story which was told and discussed by the Rotherhithe Vestry on Tuesday. A person in the locality had made himself conspicuous for many years as a vehement anti-vaccinator, and had ingeniously succeeded in evading the act, so that no members of his family were vaccinated. A couple of months back one of this man's children took small-pox. No doctor was called in, but the child was nursed by its mother and recovered. Then the mother herself took small-pox and died, after which two more of the children fell victims to the disease, and three more had to be taken to the hospital. Bad though this was, there was more to come, if the story told at the vestry be true. The anti-vaccinationist borrowed from a neighbor a suit of black clothes to wear at his wife's funeral. He kept the clothes in his house a few days before returning them. Shortly after their return their owner also took the small-pox, was conveyed to the hospital and died there. Since then several houses in the same neighborhood have become infected, and some sixteen cases of small-pox have been taken to the hospital. Commentary on such a case is needless. The liberty of the individual is sacred so long as it does not infringe on the liberty of some one else. If anti-vaccinationists only did harm to themselves no one would have a right to interfere with their fancies; but when their vagaries may lead to the wholesale infection of a district and the deaths of several persons, it is time that the laws which aim at preventing the spread of contagion should be thoroughly put into force.—*London Daily News.*

Will-Power in Sickness.—Had Mrs. Dombey only "made an effort," she would not have died. But, poor creature, she was so impotent, so listless, so effortless, that soon as ever her breath began to show signs of leaving her, she resigned to what she regarded as the inevitable; and, as a reporter would picturesquely say, turned her toes to the daisies. When her windpipe became obstructed, she should have jumped up, coughed, jocularly remarked "never say die," and perhaps she would have lived to this day. She chose, however, the more serene and becoming course of conduct, and slid down into the grave. Time and time again people have, when on a bed of sickness, come up to a point when they might easily have died, only that they were determined to live. They have set their feet, as it were, on a trap-door that covered a dark hole, but rather than sink into the hole they have summoned up a deal of courage, made a leap and passed the fatal spot. A little courage and will-power at such a time as this is worth as much as life itself, because it will often be the means of saving life.—*Herald of Health.*

Fruit in Tin Cans.—The English authorities are taking active cognizance of the dangers to which consumers may be exposed by using food contained in cans or boxes soldered in the inside and made with other than refined sheet tin. The French canneries have been prohibited by their government from soldering their cans inside, and also from using any but refined sheet tin. It has also been decided, in order, not only for the purpose of protecting the public health, but so that French trade may not be put on an inferior footing with foreign competitors, that all cans imported into France which do not comply with the new regulation will be detained by the customs authorities.

Variola in Poultry.—Prof. James Law, in the *Bulletin of the National Board of Health*, states that in Europe and Hindostan variola is so common in pigeons and poultry as to constitute a veritable plague.

SAN FRANCISCO:
Saturday Morning, Oct. 22, 1881

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Ore Roasting Furnace; Assessment Work; Apparatus for Hydraulic Mining, 265. The Week; Mining Projects that Await the Enterprise of the Future, 272. Application of Standard Measures to Industrial Processes, 272-73. The Golden Gate Park, 273 and 276. Noticee of Recent Patents, 276.

ILLUSTRATIONS.—Diagram of Farwell's Apparatus for Hydraulic Mining; Furnace for Roasting Ores, 265. Our Great Pleasure Garden—The Conservatory, Golden Gate Park, San Francisco, 273.

CORRESPONDENCE.—Butte Mountain; Bisbop's Creek, 266.

MECHANICAL PROGRESS.—A Central Power Locomotive; Heating Steel; File Sharpening by the Sand Blast; Names of Steel; Phosphor Lead Bronze, 267.

SCIENTIFIC PROGRESS.—Chemical Storage of Heat; Influence of the Electro-Disposition of Metals; Engraving by Electricity; Colored Photographs; The Value of Science; A New Carbon for the Electric Light; New Thermograph; Liquid Sugar; Eucke'e Comet; Grase Fired by a Meteorite, 267.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Noticee of Assessments, Meeting and Dividends, 268.

MINING SUMMARY from the various countiee of California, Nevada, Arizona, Dakota, Montana, Colorado, New Mexico and Oregon, 268-69.

USEFUL INFORMATION.—A Peculiar Property of Gutta-Percha; To Cover Wire with Gutta-Percha; Staining and Matching; Oil on Woodwork; "Rough on Rats;" A Vast Lead Field, 271.

GOOD HEALTH.—Concerning Mountain Cures; Death from Pricking a Sore; To Remove a Finger Ring; Civilization and Health; An Anti-Vaccinator's Fate; Will-Power in Sickness; Fruit in Tin Cans, 271.

NEWS IN BRIEF on page 276, and other pagea.

Business Announcements.

Aeeeement Notice—Franklin Gravel Mining Co., S. F.

Passing Events.

The week has come and gone without bringing with it anything especially noteworthy in the mining world. The work begun a ehort time since on the hydranlic minee has besn suffered to go on without interrnption, strengthening the belief entertained by many from the firet, that no attempt will be made to estop these operations, at least for the present.

Meantime, the committee appointed by the San Francisco Board of Trade to examine into and report upon the debris qneetion, have entered the field, and are now engaged in the active performance of their duty. Such being the case, it would be a seemly thing for the press and all concerned to abstain from indulging in tbose etrong expressions of opinion and intemperate forms of speech which have been eo apt to charaoterize the discussions of this subject on both sides. Never did a topic engage the attention of the California public that more etrongly invoked a spirit of conciliation and forbearance than this. It will be absolutely impossible to ever reach an eqnitable eettlement, or any settlement at all, of this question, without concessions and even very great sacrifices being made by both the partiee to thie controversy. It is not one in which the right is all on one side, nor yet one that ie free from many and inherent difficnlties. It would perplex the wisest judge that ever eat on the bench to decide it in accordance with former precedents, or, viewing the matter as a whole, to make up his mind as to its merits one way or the other.

The Board of Trade appointing this committee is a highly conssrvative, and, as between farmers and miners, is snpposed to be a disinterested body. With them the expression of extravagant opinione and the misetatement of facts can only serve to prejudice the cauee of tbe party making them. The impolicy of indulging such oourse must, therefore, be obvions to all.

Mining Projects that Await the Enterprise of the Fnture.

In soms allusion made by ns last week to the various forms in which the gold-bearing deposits of California occur, it was remarked that throngh this featnre the employment of many diffsrent styles of mining was hsre made possible. In recnrring to this subject it may further be observed that some of these deposits, by reason of the certainty with which thsir valne and the cost of working them can be determined in advance, prssent to that class of capitalists with whom security and permansnce are ruling considerations, attractive openings for investment.

Ovsrlooking for ths present many minor localitiss of this kind, it is our pnrpose now to speak only of a few that havs besn favorably reported npon by leading mining experts or that have otherwiss attracted notice on acconnt of their grsat magnitude or the facility with which their contents can bs utilizsd. We do not now allude to our quartz lsdges, hydraulic mining banks, drift diggings, or snch other gold beariug deposits, as are common both here and elsewhere, but to accumulations of hydraulic tailings, desp undrained flats and basins, river-bed workings, gold beaches and like unique deposits, some of which are rarely if ever mst with ontsids of California.

In our immense beds of hydranlic tailings will bs found work for many ysars, once snitable methods for handling this stuff have besn hit upon. Some of thess bsds are of great sxtent, the largest in the State bsing thoss that have gathered along Bear rivsr and its uppsr tribntaries, and in the bed of Slate oreek, the latter in Sisrra county. Great quantities of thie material have also made lodgment in Shirttail and Indian canyons, Placsr county, in Shady creek, Knapp's creek, about Cherokee, and along Humbug canyon, in Nevada county, in the bed of Willow creek, Yuba county and along many other creeks and canyons throughout the central and northern mining counties; to say nothing of the immensely greater quantities of these tailings that, having been carried farther down, have accumulated in the beds and along the benks of the Yuba, Bear, Feather, American and other rivers, but which will probably be found to contain too small a percentage of gold to admit of their ever being worked with profit.

Of the more valnable of tbese deposits, those resting in the beds of Bear river and ite branches are by far the most extensive, the whole covering a linear stretch of more than 20 miles, and containing a total of at least 100,000,000 cnbic yards. Thie etuff is estimated to contain from 15 to 20 cents to the cnbio yard, giving to the whole a value of say, $20,000,000. Of this amonnt it is believed that 75% can be saved at a comparatively small expenditure on working acconnt.

At first it wae proposed to run off these Bear river deposits by means of a tunnel to be driven through the ridge that separates this stream from the North Fork of the American river, emptying them into the latter; a project that at one time seemed feasible. The floods that annually occnr in this river have, however, carried away so great a proportion of tbe lighter particlee leaving these tailinge to consist at present so largely of coarse gravel, shingle and bowlders that it ie feared thie heavy material could not now be run down into and passed through a tunnel without a larger amount of water than could here be readily commanded, the fall in Bear river being eo inconsiderable. In view of this difficulty the plan of working these tailings with the hydraulic elevator hae been recommended and will probably be adopted, as this machine is now being employed npon eimilar deposits at Willow creek, and elsewhere in the State with entire enccess.

The tailings resting in the bed of Slate creek cover a linear extent of 10 or 12 miles to an average depth of 30 and a width of 100 ft. The idea has been entertained of rnnning ont these tailinge by cutting away the rocky barrier at their lower end, which, having originally estopped them, etill prevents their escape. Ae this would be a costly experiment, and not eure of answering the end proposed, it is more probable that recourse to the hydranlic elevator will here also be had when the time comes for handling this material.

The plan of making open cnts through the rocky obstructions, to the presence of which the existence of these deposits is often due, is now in lese favor with mining engineers than formerly, these cuts having sometimes failed to accomplish the object they were intended to subeerve, and, where effectnal, their constrnction having generally been attended by greater expense than was at the etart anticipated. Thns, the open cnt bronght np to secnre outlet to Indian canyon, cost some $35,000, fully a third more than was originally eetimated. After an outlay of $70,000 in attempting to cut through the granite reef at the lower end of the Willow Creek deposits, the work was abandoned, as reqniring too much time and money to effectnally bottom the basin above, though it is known to be one of the richest in the State. In view of the experiencee had in dealing with this class of deposits, it may be concinded that the above method will be generally snperseded by the hydranlic elevator as a means of working them in future.

In our alluvial flats and basins we have another of these sonrces of reserved wealth waiting on capital and the enterprise of the futurs for development. The most of these loealities being walled in with rim-rock can be drained only with lengthy tunnels, works too expsnsive for individnals or small companies to undertake. As a consequsncs, hut few of them have as yst bsen opsned up, some of the tnnnels started for that purposs remaining uncompleted. Of thsse auriferous basins, one or two of those considered the most promising, are snpposed to exist in Tuolnmne county.

Last fall a company commsncsd lifting and rnnning off, witb a hydranlic elevator, tbe contents of the Yrska basin, an extensive allnvial flat in Siskiyou county. Tbough mesting at first with the troubles incidsnt to the nse of a new and imperfect mschine, the company are now reported to be doing well. An operation of like kind has bsen in progress for more than a year past at Ohio Flat, in Yuba county, whsre several acres of gravel covered with tailings have been run off with such sxcellent results, that it may bs expected others of these deposits will, in like mannsr, bs attacksd befors long, there being scarcely a county along our main gold belt bnt what contains some of thsm.

A projsct has lately besn set on foot and is now being matnred for disposing of the top gravel in Weaver Basin, an immense bowl-like depression in Trinity connty, known to be rich in gold. The consummation of this schems involves the construction of a large tunnsl through a psninsular ridge formed by a long bend in ths Trinity river, whereby fall enongh will be obtained to run off a largs amount of surface gravel in this Basin, though not by any means enough to bottom it, as it is known to be over 600 ft. deep. This latter objsct can only be effectsd by means of anothsr and much longer tunnsl, tbe construction of which it is believed will some day be nndertaken, as a work of this kind would be entirely feasible and very likely accomplish the end proposed. Conjoined with the first of these schemes, will probably be the exteneion to Weaver Basin of the large ditch now being built by Thomas H. Blythe, for conducting the water of Coffee creek and other large branches of the upper Trinity, npon tbe mining grounds of tbe proprietor and others adjacent. Viewed as a whole, this enterprise may be considered one of great magnitude, as well as one likely to lead to a scccessful issne.

Among the varions schemes projected for diverting the water from long sections of the river beds, thereby so draining the same that they can be readily worked, that for turning the Feather river above Oroville is the most extensive, as well, perhaps, as the most promising and practicable, as a tunnel a little more than one mile long would lay bare over 10 miles of tbe river bed, which, there is reason to believe contains a great deal of gold. A compsny has been formed within the past year to take hold of this work, which, it is eaid, will soon be commenced. Along most of the large rivers in the mining regions of California opportunities present for inangurating eimilar enterprises.

What, if anything, is to be done toward more largely utilizing our auriferous beach sands is a matter not so easily to be determined. That something will yet be accomplished in that direction may be assnmed, seeing how generally successful we have been in our contest witb the many seemingly insnperable obstacles that we have been able to overcome in tbe history of gold mining in California. Having effected eo much, the present generation may fairly leave to the legatees of these great bequests tbe solntion of eome of the difficult problems that go with tbe inheritance.

Two Claims on Same Ledge.

By the following ruling of the Land Commissioners it will be eeen that the U. S. Land office will conntenance a locator in taking up two claims on the same ledge: In reply to your letter asking whether yon will be allowed to locate two or more claims upon the eame lode, which yon eay wae discovered by you, I have to call your attention to the fact that section 2320, Revised Statntes, declaree that:

"A mining claim located after the 10th day of May, 1872, whether located by one or more persons, may equal, hnt shall not exceed, 1,500 ft. in length along the vein or lode; but no location of a mining claim shall be made until the discovery of a vein or lode within the limits of the vein located."

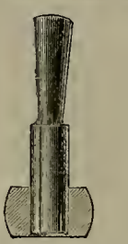
There is no provision of law, however, to prevent partiee from locating other claims npon the eame lode outside of the first location made on the vein or lode. If a vein or lode 3,000 ft. in length ie discovered by a party, two locations may be made by him thereon, each 1,500 ft. in length. A full compliance with the reqnirements of the mining laws will, of course, be necessary in the case of each claim or location before the patent can be issned therefor.

WORK FOR ALL.—Since the hydraulio mines recommenced operations, the hnndreds of men who were thrown ont of employment when operations were euspended, and did not possess the means to get away, have gone to their old places once more. Those who left the county at the time are gradually drifting back again. Employment is fonnd for all worthy applicants, and the demand is mnch greater than the supply at present. The forces at one of the minee will be incrreased some 300 men within the next 30 days. The best part of all is that Chinamen cannot obtain work ot any kind.—*Nevada Transcript, Oct. 14th.*

Application of Standard Measures to Industrial Processes.

[Continued]

It is a remarkable fact that San Francisco is perhaps ths only largs city and manufactnring csnter within this country or Europe where Standard sizes ars not followed. There is a progressiveness in engineering work here that makes it very strange to find ganging implemsnts not conforming to our National Stsndard, and dimensions employed in other parts of the conntry. Most of the works hsre have gauges of a special kind, varying from one another in the varions shops, so as to rendsr interchangs impossibls, and varying also from the trne standard. In soms casss not much, but in all enough to causs confusion. The engraving shows the common form for such gauges.



Iron hsre is rolled to the same dimensions employed elsewhero. Is, indeed, in most casss from ths seme etock used in the Eest. So there appeare no reaeon for not following Standard dimensions, unlese it be the old obeolete idea of compelling cnstomere to rcsort, for repaire or additions to the seme shops whore work was originally made. That, as an economic or business expedient, ie no longer followed elsewhere. We have secured the gas-pipe trade in Canada, as well as some other countries, because the British too long kept to the expedient of making special eizes at the different works. I remember, when a boy, to have visited a mechine shop in this country, where en English manager caused the sorew-threads to be made of fractional pitch; that is, an uneven number of threade to each inch of length, so othere might not repair his work. I have recently seen the same place where that works stood. There are otber kinde of business carried on there now. It causes very little confusion or expense to adopt standard eizss, and there is no donbt, in time, the worke here will do so, especially if the value of machinery is affected by the matter.

After what has been explained in respect to the exactnees necessary in dimensions, it will not be a wonder that Standards are so carefully prepared and carefully kept at Paris, London and Washington. The twenty-thousandth of an inch will not seem a refinement in au original Standard, to be employed in references when work itself is made within one ten-thousandth of an inch.

The fact is, that all the care and precision taken and hereafter to be explained, is no more than ie reqnired; is indeed lese in some cases because an error or variation in one of our National Standarde was detected or suspected abont two yeare ago. The Bronze yard taken from the Imperial Standard at London. Thie bar was taken to Europe by Prof. Hilgard, for the purpoee of comparison, but the result has not so far as I know been made public in this country.

With this much in respect to the economio valne and practical use of Standard measures, I will now pase to their derivation, or rather their adoption, for as a matter of fact none of them are derived. All length Standarde in the world are arbitrary. The ingenuity of man has not thne far succeeded in finding any natural Standard from which constant dimensions could be derived.

There have been numerons attempts, bnt none of tbem enccessful, and the legalized Standarde with which we are familiar, the meter and yard are specific rods of metal to which legal acts apply, irrespective of how their length was determined or the relations of that longth to other dimensions.

Speaking of natural Standards it ie etrange that Nature with her harmony and unerring laws, lacks the qnality of nniformity.

No two things are alike. Among hnndrede or even thousands of persone we may know, there is difference enough to recognize each at a glance. In the billion of human beings on thie earth, perhaps no two are precisely identical. No two animals or plante are alike—not even two leaves, if critically compared. Everything is changing; nothing ie conetant and uniform in nature except the movements of the celestial bodies, or time. Time is always the eame. We have a perfect, natural Standard for that, and ingenuity hae almost snceeeded in deriving lineal measures from time, bnt has not quite snceeeded.

A pendnlum swinging freely always beats in nniform time, ae its length, and irrespective of the distance or range. This has for a long time been known as a scientific fact. Mersenne, an Italian, in 1647, proposed the pendulum test as a base for lineal measure. It has also bsen known that a pendulum 39.13 inches long would beat seconds—60 times in a minute. It was for a long time thought that a poeitive nnit of

length could in this manner be obtained. The meter is in fact almost the length of a second pendulum, being 39.37 inches. It was not, however, derived in this manner.

If three pendulums, one at St. Petersburg, one at San Francisco, and a third at Calcutta, were arranged to beat seconds, and the lengths of these pendulums could be transmitted to metal rods like the Standard yard, then it would be possible to produce a unit of length the same at these widely separated points. Moreover, such a length would, in a sense, be a natural one, derived from natural sources, but these pendulum tests do not always lead to uniform results. One difficulty, almost an insuperable one, can be imagined, by asking the question, where is the bottom end of a pendulum? The point of suspension might be definite enough, but the center of gravity, the center of percussion and other conditions cannot here be determined so as to fix the other points. In such tests parallel rods are employed having two axes inserted, one at the bottom and the other at the top. After the pendulum has been adjusted in one position, it is reversed, the bottom end being placed at the top, and *vice versa* until in either position the oscillations are performed in one second precisely. But even this is not enough. Points on which a pendulum swings or indeed any point made of metal, is not fine enough to compare with the minute lines employed in Standard measures, and much less with the end contact bars such as are prepared at Washington.

The yard is our unit of length. It was wisely taken from the British Standard, thus saving us a good deal of expense and trouble and rendering our Standard doubly secure, because if those in Washington were destroyed it would be easy to secure copies from England. So long as one arbitrary length was to be adopted, it could make but little difference what that length was, and having already the divisions of the yard, feet and inches, in use, it would have been very foolish to have set up a new standard in this country.

In some engineering books an American Standard is spoken of, and the difference between that and the English is given. I have been able to trace this to a suspected source, in some imperfect divisions attempted at Washington, before any of the present apparatus was prepared.

There is in this, and I presume all countries, an unfortunate few who can see no reasons for adopting from other countries what is good and useful. Among that number are those who would prefer to see some new lineal standard set up in this country, differing, if possible, from all others.

The Imperial yard being our standard, some history of its origin will be in place here. We all remember in our old tables: "three barleycorns make an inch." This was an old statute in England. "Three barley corns hulled dry and laid in a straight line," are, nevertheless, a very uncertain length, and this matter is mentioned to show how indefinite were length Standards at the time—about the year 1700. The foot, formerly used in at least seven different European countries, besides Great Britain, was the traditional length of the "king's foot." The foot measure varies from 12.07 inches in Holland to 11.2 in Russia; so the lineal foot is like its human antecedent, of various lengths. The English yard of three ft., or 36 inches, appears in cloth measure, long measure, land and cubic measure. It is the true British unit and is not too long for a Standard. The history of the yard as a Standard, or unit of lineal measure, dates from 1742, when the Royal Society, in England, employed a mechanician, of London, to prepare a brass rod and mark it with the length of a Standard yard. From this rod two copies were made, and one of them adopted by a committee of Parliament, appointed in 1758. No act was passed, however, legalizing this Standard; and another Parliamentary committee was appointed in 1790, to consider and report on a National Standard of lengths. This committee, however, did nothing, and the whole matter rested until 1814. During this time there was much consideration given to the subject by scientific men and learned societies, mostly in the hope of devising means to duplicate or reproduce the yard should the true Standard be lost.

Such consideration as you may infer from what has been explained, was mostly in attempting to find some natural and constant test like the pendulum one.

The committee of 1814, the fourth one counting the royal societies of 1742, recommended the adoption of one of the copies from the old Royal Society yard, and at the same time as a comparative standard recommended that the length of a second's pendulum should be assumed as 39.13 inches long. In 1819 a Crown Commission was appointed to again investigate the matter. This committee after three year's consideration again recommended the adoption of the old yard, and also gave as a constant for weight one cubic inch of distilled water as 252½ grains, and the second's pendulum with a variation of one ten-thousandth from the former report of 1814.

The variation in respect to the pendulum test excited some anxiety, but the old yard was legalized by act of Parliament in 1824.

In respect to this, as has once before been pointed out, the act did not deal with any length or establish a certain unit, as that could be no more than a name; it confirmed a certain metal rod then present, and identified as the Standard of the Nation.

A copy of this rod was procured by our Government and deposited in Washington, where it was known as Bird's Standard, having been made by an optician in London of that name.

Ten years later, in 1834, this famous yard, the result of so much experiment and expense, was burned in the House of Parliament, and as the copies were not considered exact, the whole matter was again to begin anew.

A Treasury Commission was appointed in 1838, who decided against the pendulum test. These commissioners had the matter under advisement until 1841, when it was decided to restore the old yard as nearly as possible from existing copies, and to abandon all attempts to qualify that length by natural Standard of any kind whatever.

Again was appointed a new Government Commission, making, I think, the seventh one; this time, however, composed of men able to deal with so technical a matter.

The aid of mechanicians was called in. M. Sheepshanks, a celebrated mechanic and scientific man, of London, spent 11 years of his life constantly engaged in experiments on material and to derive from the various copies at hand the nearest approach to what the lost Standard had been.

Tens of thousands of readings and comparisons were made. The adjustments were so fine that the variation of one one-hundreth part of a degree of temperature sensibly affected the rods experimented upon.

It will be difficult to understand why all this labor, expense and precision were required, and that so much time should be consumed in experiments. I am not able to explain all this, but know that experiments on material to find that which was uniformly affected by changes of temperature was one thing.

Mr. Airy, now Sir George Airy of the Royal Observatory, at Greenwich, was also engaged in the work which was finally completed in 1855 after 14 years of labor.

Four copies were made of the Standard yard. They are bars of solid bronze 38 inches long and one inch square. One inch from each end is drilled a hole about three-fourths the whole depth of the bars; in these holes are inserted pins or plugs of gold, their top coming level with the central axis of the bars.

Across these pins are engraved fine microscopic lines, one yard apart.

One of these Standards is deposited in the Royal Mint; one was given in keeping to the Royal Society; a third was placed in the Royal Observatory at Greenwich, and the fourth was buried in the lower waiting hall of the present houses of Parliament.

An act legalizing these Standards was passed in 1855, more than 100 years from the time the subject was taken up, and the matter is now at rest no doubt for generations to come, because if any new unit, the meter for example, were adopted in England or this country, its length would be defined by the Imperial yard.

"What a bother about a yard stick" is the thought no doubt of many who first hear of this long search for a Standard, but he must remember all this was done by a very practical common-sense people who thought the end worth the means. One incentive perhaps to this very careful preparation of a Standard was in emulation of the French.

(To be Continued.)

Disastrous typhoons occurred last month in China and Japan.

The Golden Gate Park.

A few years ago the outside lands of San Francisco, westward from Devisadero street, were often the source of fierce contention for possessory right by various parties, not unfrequently resulting in bloodshed and death to the retainers of adverse claimants. How long this state of affairs would have lasted it is hard to say, had not some far-seeing persons succeeded in having a portion of the land in question sequestered and finally, by legislative enactment, devoted to public use in the shape of parks. The property once secured, it was not long in being turned to account. With this end in view, the Governor was authorized and directed, within 30 days after the passage of the act, to appoint three Commissioners, who were to hold office for four years without compensation, each Commissioner to be a freeholder and resident of San Francisco. The first Board of Commissioners was composed of Messrs. S. F. Butterworth, D. W. Connelly and C. F. McDermot, and to them and their successors our city will ever be greatly indebted for what is now the most delightful resort on the coast. We have never heard what

OUR GREAT PLEASURE GARDEN—THE CONSERVATORY, GOLDEN GATE PARK, SAN FRANCISCO.

the gentlemen had to say on being shown their field of labor—certainly nothing could have been much more uninviting.

The grant consists of a parallelogram about three miles in length by half a mile in width, and contains in the neighborhood of 1,050 acres, of which fully three-quarters were desolate sand dunes, relieved here and there with a hill of red rock suitable for making roads. In fact, it was a miniature Arabia—there was *Stony* and *Sandy*, but the third part was lacking. Kind nature, with bountous hand, had decked no portion of it with lofty trees and luxuriant herbage, and the lonesome traveler derived but little comfort and society from the presence of vegetable life. Out of such an allotment how nearly has been constructed Arabia Felix, may be ascertained by spending a day within its bounds. Noonday and midnight are not more opposite than

What it Was and What it Is.

It seems to be an institution created for the people, and a more cosmopolitan thing than its visitants can hardly be found. Representatives from every class and condition of society enter its portals, and the gay equipage of the millionaire often presses hard on the tattered garments of Lazarus. During the year just passed the gatekeepers have reported the entrance of the following: Carriages, 42,745; double buggies, 47,070; single, 170,302; total vehicles, 260,117; equestrians, 37,526; pedestrians, 834,863; in vehicles, 780,501; total, 1,652,993.

For the accommodation of these visitors there has been constructed (linear measurement) of drives and bridle paths, 48,682 ft., covering an

SECURE PATENTS

Through Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

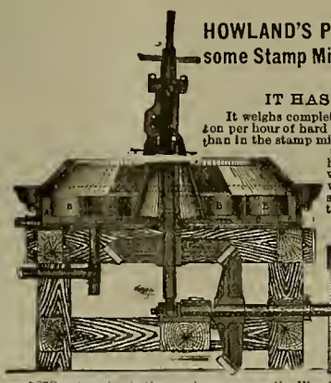
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteeian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

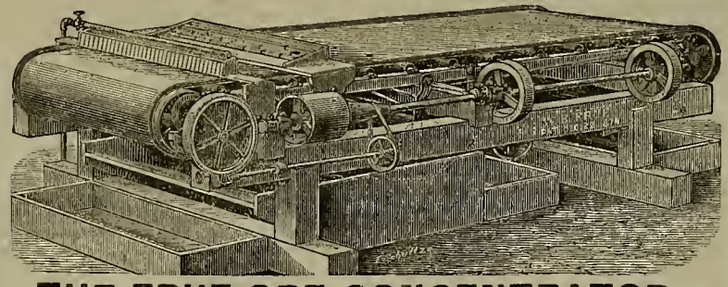
MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery



HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also

SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞ Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.
Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.
We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.
☞ A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.
ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

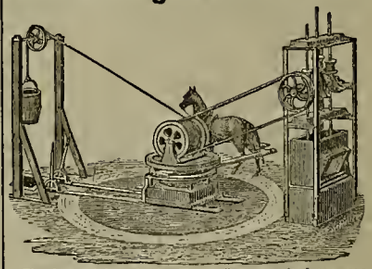
New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING OCTOBER 4, 1881.

247,862.—LOCOMOTIVE—John T. Davis, S. F.
247,749.—ORE CRUSHER AND PULVERIZER—W. L. Dawson, S. F.
247,867.—DUMPING WAGON—Jos. T, Dougine, S. F.
247,769.—PREPARING AND APPLYING CIGAR TIPS—A. J. Lachman, S. F.
247,941.—SCRAPER—Jas. C. McIntosh, Stockton, Cal.
247,781.—CABLE RAILWAY—Henry Root, S. F.
247,868.—FEED CUTTING MACHINE—John Weichart, S. F.
247,788.—WOOD PLANING MACHINE—Asa R Wells, S. F.
248,000.—ROTARY CYLINDER FURNACE—Geo. W. White, S. F.
247,863.—PUMP—M. W. Wilkins, Corvallis, Oregon.
247,976.—BOAT DETACHING APPARATUS—Albert Willis, Colusa, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

AMALGAMATOR.—N. D. Burlingham, Garden Valley, El Dorado county, Cal. Patented, Sept. 27, 1881. No. 247,535. This invention consists in the following construction and arrangement of an ore amalgamator: Suitable means are provided to prevent the mercury rising in the water duct which opens into the mercury bath, and which may be effected by hydrostatic pressure or by other known ways. Open pipes or stirrers are oscillated in the mass of pulp within the tank, and streams of clear water are ejected from the lower ends of said pipes, onto the surface of the mercury so as to keep it free from slimes and dirt, and the pulp is at the same time stirred up. The peculiar shape of the tank gives the precious particles an opportunity to settle. The oscillating arms or pipes are operated by a water wheel which is run by the overflow of waste water from the tank. Copper plates are placed on the tank sluice, which extends from the tank, and also upon the blades or buckets of the wheel, so that all particles of gold and quicksilver are saved. Under the tank is placed a receptacle for any appropriate heating device, whereby the mercury may be kept at a proper temperature in cold weather.

AMALGAMATOR.—A. R. Hamlin, Alameda, Cal. Dated Oct. 11, 1881. No. 248,171. The object of this device is to provide an efficient amalgamator in which the access to the interior is easy, whereby the mercury baths may be moved when required, and the tube cleaned; and it consists of a serpentine tube or pipe formed in sections of gradually decreasing curvature properly joined and having a hopper, into which the pulp and water are fed, whereby pressure is obtained sufficient to force the wet pulp through the tube and through the mercury baths in said tube.

ROAD WAGON.—E. B. Towl, Franktown, Washoe county, Nevada. Dated Oct. 11, 1881. No. 248,235. Under the forward part of the frame of this wagon is a box in which is journaled a shaft, the ends furnished with cranks to which any suitable power may be applied. The shaft carries a double gear which engages with pinions journaled in each side of the box. These pinions have secured to them forked heads which fit into similar forked heads formed upon the ends of tumbling rods, thereby making a joint adapted to be moved to either side and up and down, yet not permitting either piece to be turned independently of the other. This construction is preserved throughout the train of wagons.

FRUIT BOX.—Robt. J. Cooke, Sacramento, Cal. Dated Oct. 11, 1881. No. 248,143. This invention relates to improvements in that class of boxes or baskets which are made of thin, light material or veneer, and which are generally used for packing berries, grapes and small fruits. It consists in the construction of a double floor, the inner portion of which is perforated and is sufficiently distant from the other to allow a free circulation of air between the two.

MINERS WANTED.—As will be seen by reference to an advertisement in this issue of the PRESS, the New Almaden quicksilver mining company are in need of 200 miners. As the company is financially strong and the site of their mine an exceptionally healthful and pleasant one, this want ought to be readily supplied by first-class miners, of whom there are just now a good many unemployed in California. Locality of mine, near San Jose; principal business office of the company in this city.

MORE OIL.—The oil interests in Santa Paula canyon, Ventura county, are said to be reviving. Contracts have been let for boring five wells.

Golden Gate Park.

(CONTINUED FROM PAGE 273.)

area of 2,055,630 ft., and of walks for pedestrians, 10,000 ft. This does not include road making done by the Bush fund.

These walks and roads have been on every hand embellished by the gardener's art, until, in her gay attire, the park enfolds a vast variety which is pleasing to the human mind, and consequently has a tendency to tranquilize the agitated passions, exhilerate the man, and render all around him delightful. Here he who has been confined with the business of the week, toiling in the "sweat of his brows," becomes invigorated and refreshed as he takes his walk, with the happy family group about him, and marks how the desert has been made to blossom as the rose.

The Conservatories.

This structure is favorably situated on a commanding site between the main drive and the north ridge road. The building is about 250 ft. in length, covering an area of about 15,000 sq. ft., and exceeded in size only by the Government conservatory, at Washington. Oriental in style, graceful in outline and highly ornamental. The main entrance, or reception-room, is 23 ft. square, substantially furnished, and ornamented with a fountain in the center. From this room the visitor enters the rotunda—a circular room 50 ft. in diameter and about the same number of feet in hight. An octagonal space in the center of the rotunda is occupied by several varieties of rare tropical plants; and the dryness of the atmosphere is relieved by the spray from a fountain set in the center of all.

On the right of the rotunda is the Orchid house, an arched room, 35x50 ft. There are many rare and beautiful varieties of this strange family to be found here, representing a monetary value of hundreds of dollars, principally the gift of our public spirited citizens. The space not all being taken up by the orchids, an infinite variety of other beautiful flowers have been introduced, presenting the great difficulty of deciding which is possessed of the greatest charm; yet certainly, nothing can be much more beautiful than the collection gloxinias here assembled. The beauty of the flower steals upon one, and almost before we are aware of it, we are absorbed in admiration.

The arched room on the extreme right of the building is set apart for the cultivation of the larger and rarer aquatic plants. A circular pond, 28 ft. in diameter, has been constructed here, with the necessary heating apparatus, and the general public already know the result. In this tank the Victoria Regia lily reigned supreme, surrounded by the less pretentious, yet still beautiful sisters of her tribe.

The Ferns.

Although not confined to any one portion of the conservatory, more may be found adjoining the lily pond than anywhere else. The collection comprises all the finer varieties, such as tree ferns, staghorns, climbing ferns, adiantums, and in the more sheltered nooks the magnificent Farleyense shows how beautiful a thing may be yet bear no flowers. There is probably no form of growth that attracts more attention than ferns. Their delicate foliage causes them to be sought for cultivation, or their fronds are carefully gathered and dried by the ladies against the time when occasion offers for spatter-work. They furnish to botanists a broad and inviting field for investigation, but their greatest beauty can be brought forth only with the microscope. Thus they appeal to the scientific element of man's nature as well as to the æsthetic, and while they gratify the taste, furnish food for the intellect.

We doubt the existence of a superior floral display anywhere in the world, and a 30-year old city being the possessor of it must commend, abroad, our admiration of the beautiful, as well as the public spiritedness of our citizens.

On the left of the main building is a wing similar in size and shape to the Orchid house, in which may be found some of the choicer varieties of roses, such as Mareschal Neil, Cloth of Gold, etc., together with azaleas, lilies and a multitude of beautiful foliage plants. The Californian, having grown tired of exotics here, recognizes an old friend in our beautiful Mariposa tulip, cultivated and brought to perfection, and it is at once placed in the front rank of flowers.

The greenhouse adjoining, which corresponds in general features with the aquatic department, is intended for the growth of hard-wooded plants, such as japonicas, azaleas, etc. Here, apparently with a desire to show what may be done, the gardener has taken several heliotropes and trained them to standards, until they have attained a hight of from 8 to 10 ft., without a sign of vegetation on the stem, until the top is suddenly terminated in a magnificent umbel of flowers, as delightfully fragrant as only heliotrope can be. There is also an old-fashioned rose geranium trained in the same manner, to a hight of 18 ft. The lover of camellias will here have no cause for complaint. This room probably presents the greatest diversity of color to be found in the building, for here are stored the calceolarias. This collection (calceolaria) does not command attention so much for its beauty as for its abundance of flowers and variety of hues; among scores of plants, no two being found of the same shade. The border plant, the Alternanthea amabalis (?), being easy of cultivation, pleases everybody, and is one of the finest edging plants that can be grown.

In the rear of the building are two propagating pits, 50 ft. long by 12 ft. wide; a growing house, 75 ft. long by 25 ft. wide; and a potting-room, 30 by 30 ft.

A heating apparatus supplies the requisite warmth to all the chambers, and an admirable system of ventilation enables the keeper in charge to preserve at all times an equable temperature.

Thirty-five tons of glass and over three tons of putty were used in the construction of the conservatory.

The Commissioners have lately received from Sir Joseph Hooker some 65 varieties of Sikkim and Bootan rhododendrons, the finest and choicest of the family, many of which will have to be grown in the conservatory to be protected from the prevailing winds.

The Attributes of Mining.

An article recently appeared in the Salt Lake *Tribune* which is truthful in many ways as regards the industry and consequent effects of the search after the precious metals. It truthfully asserts that the man who tries to make a livelihood and a fortune by mining for gold and silver has a pretty hard time. It is true that he has to purchase everything with which to prosecute his work, and equally true that if he succeeds, all he gets is so much added wealth to the country, and that it comes in a form which not only does not endanger the sale of any other man's product, but rather helps every other man in the community. Still, if the fairest prospects fail and he loses his all he gets very little sympathy, while if he succeeds the finger of envy is sure to point to him, and the declaration is made that, "he, without any particular sense, stumbled on a fortune," or that "he got rich in a stock swindle." And yet mining is the only thoroughly legitimate business that can be engaged in between the Rocky and Sierra Nevada mountains. That is, it is the only leading interest. All others, at least the prosperity of all others, depend upon mining. Take it away, and Idaho, Montana and Nevada would become mere stock ranges, and the coyotes would bark, undisturbed, at the locomotives of the overland trains. In its influence mining extends beyond all industries. When from the West wheat is shipped to the East, and a million of dollars is paid for it, it is only a species of barter after all. The world at large is no better, except that it has a little more food supply, which amounts to nothing, because a few strong arms or valueless hands can raise it in a single season. But when a million of gold is taken from the earth, there is a creation. The world is that much richer in something which it did not have before, which is indestructible, and which is so rare and so much prized that all races, civilized and savage, receive it at its established value. Again, let there be a double wheat crop raised in any single year, and the value of wheat lands would fall, because wheat raising would be looked upon as an unprofitable business. But let there be a double yield of gold and silver in the far West in any given year, and all over the far East the price of real estate would advance, because gold is chiefly valuable because of its rarity, and the more there is the more it takes of it to make a measure of values for other property. The gold of California, while it enriches but a few Californians, doubled the value of lands in the Eastern States, over whole States, while to the arteries of commerce, before so sluggish, it operated like a transfusion of new and healthy blood. And when the war of the rebellion was sore, the gold and silver of California and Nevada were the pivot on which, perhaps, the mighty war turned. The men of the East should remember these things, and should reflect that mining is not barter like the ordinary business of life, but the creation of wealth. Its success is more than the making rich of the miner; it quickens the pulse beats of trade to the remotest extremity of the Republic.

News in Brief.

JOHN W. CARROL, the actor, is dead.

SMALL POX and typhoid fever are raging in Chicago.

GAS works are to be erected at once in Tucson, A. T.

SENATOR MAHONE has decided that Gen. Early is beneath his notice.

FLOUR is selling at $15 per 1,000 lbs. at the Eagle mills near Ashland, Oregon.

THE recent hurricane in England and Ireland did immense damage to property.

A NEWSPAPER is to be started at Mandan, Montana, on the Northern Pacific.

THE steamer *Great Eastern* is to be sold again. She is the white elephant of the sea.

SOME 200 Postmasters will, it is alleged, be implicated in the Star route frauds.

LOCAL Independent movements exist in a majority of the counties of Mississippi.

A WASHINGTON correspondent says President Arthur is more taciturn than Grant was.

NINETEEN miles of track are already laid on the California Southern from San Diego.

THE Mississippi river is again on the rampage, and fears of great damage are entertained.

A steamship capsized in the drydock at New York, badly damaging her and killing one man.

ARRESTS of prominent Land Leaguers continue in Ireland, and the excitement is intense.

THE railroad up the Nile is progressing, and already the cry is heard "all aboard for Sahara."

A NEW channel is to be made for the Yuba river, intersecting the Feather at the old '49 town-site of Eliza.

THERE are 55 quartz mills in Arizona aggregating 585 stamps, only one of these mills being run by water-power.

MEXICAN troops are marching to the Arizona border, to co-operate with the American forces against the Apaches.

CAPT. H. H. RINGLEBERGER and Hon. G. D. Wise fought a duel near Richmond, Va., in which neither was hurt.

THE Standard Oil Co. has been sued by the State authorities of Pennsylvania to recover $3,000,000 in taxes and penalties.

PERRY STUCK, an old time stage driver, lately committed suicide in the stage stable at Jackson's ranch, Little Porcupine, Montana.

SECRETARY BLAINE has again notified the President that he would gladly be relieved of his official responsibilities at once.

EDWIN BOOTH and his wife have separated, the estrangement being caused by certain business transactions within the family.

THE Indian charged with killing the Perkins family has been found guilty at Yakima City, W. T., of murder in the first degree.

A MILL is about to be erected at Cornicopia, Nevada, for working the tailings of the Leopard mine of which there are about 200,000 lbs.

CAPT. SYLVANUS SWAIN, aged 82, and a pioneer, died at Martinez a few days since. Capt. Swain sailed up the Pacific coast 53 years ago.

THE Government work on Coos bay extends from the shore of Rocky Point into the bay upward of 1,300 ft. At the outer end the water is 26 ft. deep.

SAM DODGE and Jim Aelic, two Indians convicted of the murder of Ezra DeGarmo, in Amador county, have been sentenced to be hanged December 8th.

THIRTY murderers are in jail in Philadelphia, awaiting trial, and it is thought that not less than half of them will be convicted of murder in the first degree.

TWENTY-SIX Mormon missionaries will leave Salt Lake City on the 18th inst., for Europe, to make converts, chiefly in England and the Scandinavian countries.

THE jail of Eureka county, Nevada, is empty, a thing that has not occurred before for a long time.

THE gale which caused such damage in England and Ireland extended to France and Germany.

EX-GOV. IRWIN has repurchased his old paper, the Yreka *Tribune*, and resumed the editorial harness.

THE settlers upon the Upper Columbia river, in Washington Territory, are constantly agitating the matter of completing the locks around the Cascade, in order that they may have open highway to the ocean.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Business and Patent Offices Removal.

After October 29th, our friends and patrons will find the business offices of Dewey & Co. removed from No. 202 Sansome St., to No. 252 Market St., on the northeast corner of Front and Market Sts. We have secured the entire upper floor of Nos. 250 to 252 Market St., and No. 12 Front St., where we shall have permanently more spacious and pleasant rooms for the accommodation of our increasing business. Our apartments will have two main entrances as shown in the following engraving, viz:

OUR STAIRWAY, No. 252 MARKET ST.
OUR ELEVATOR, No. 12 FRONT ST.

The building we have now occupied between four and five years is to give place to a new one, which fact causes our removal.

Old and new friends are cordially invited to give us an early call in our new quarters.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F.D., at this office.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

San Francisco Metal Market.

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

THE O'HARRA

CHLORIDIZING FURNACE.

Patented in 1878.

SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenial sulphurets of silver up to from 84% to 95% of the assay.

TONITE POWDER COMPANY, - - 403 California St., S. F.

Good Land and Sure Crops.

There has been steady and tolerably rapid advancement made in the growth of a majority of the towns in Colusa, Butte, Tehama and Shasta counties. Especially is this so in the agricultural districts where the land produces at least fair crops in all seasons—wet or dry—as does the land on the Reading Ranch. Those looking for homes in California where diversified farming will pay every year; where wood and water are plenty and easy to be obtained, and other desirable advantages are to be had, should address the proprietor of the Reading Grant.

Some 14,000 out of 26,000 acres of the grant remain for sale at comparatively low rates, in quantities to suit purchasers, on easy terms. Prices range from $5 to $30 per acre. The tract is between two and three miles wide, with the Northern Division of the C. P. R. R. passing centrally through its entire length. Send postage stamp for free circulars containing information about Shasta County and these lands, to the proprietor of Reading Ranch.

VOLUME XLIII Number 18

Application of Standard Measures to Industrial Processes.

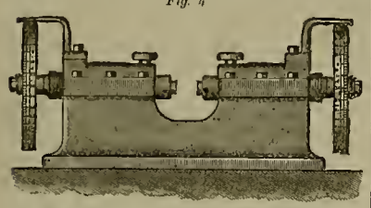
[Continued.]

In 1792, they made carsful measnrsments of a dogree of msridian hetween Dunkirk and Barcelona, and by snhdivisions cstahlishsd the famons mstsr, then thought to hs ono ten-millionth part of a quadrant of meridian, or ons forty-millionth of the circnmferenco nf tho earth at the msridian. Thie, yon will perceive, was an attsmpt to derivs a standard from natnrs or from natural sonrces. It was, howsvsr, found in future computations that this was not reliahle, and if tho meter were lostit could not he restored with precoision, or in a manner to claim popular acceptance; so that in 1795 the French Republic passed a decres estahlishing ths length hetween the ends of a certain har of platinum to he a mstsr and the National Standard. This meter, as hefore explainsd, is 3 ft 3⅜ inches long—not precisely, hut the difference is not mors thsn fonr tsn-thousandths.

Sir John Herschel propesed that the earth's polar axis hs adopted as a hasis from which a unit should be drawn, hut ths failure in former schemes of ths kind prsvented any action respecting his plan.

After thess explanations you will he ready to agree that our Governmcnt, as hefore remarked, has been wiss in not attsmpting to search for natural Standards or to vary from those now estahlished. The time and monsy that might havs thns heen wasted have been wisely put to a hsttsr nss in prsparing apparatus for comparing, transmitting, dividiog, and so on—

Fig. 4.



apparatus that has no equal in ths world; in effi ciency and completsness, at least.

This ends what I will say ahont Standards and their derivation, and hrings us to what may he called apparatus of transmission or comparison In othsr words, to implements hy which ths Standards nf length are applied to industrial purposes. The limits of my lecture will admit of noticing only a few of ths varied means employed, and these for the most part original or testing implcmsnts.

As hefore rsmarked, there are two means of comparing measursmcnts—ens hy sight and ons hy touch. In msasuring machines, the lattsr is generally spoken of as end contact.

Sight is hoth more and lsss exact than tonch. We cannot well see divisions of less than onsfiftisth of an inch with ths naksd eye—that is, cannot see thsm so as to he counted and nsed. One-hundredth of an inch can he seen on a stesl rule, hut not counted. This then is the limit of sight in so far as looking at lines without glasses, hut touch detects variations to one tweuty-thousandth of an inch. There is perhaps no one present who could not detect a difference of that amount hetween two calipers like this in an experiment. The sensitiveness of touch is wonderful. I am not prepared to say what its limits are even with ordinary tools, not gauges, hut common calipere and the like. As a matter of conjecture, I will eay one fifty-thonsandth of an inch.

The application of sight to determine lengths or comparisons, "readings" they are called technically, can he divided into three methods, namely: (1.) Observing marks or lines, as on a common rule, with the naked eye. (2.) Obssrving fine lines hy means of magnifying glasses. (3.) Observing by magnifying movement, or magnifying quantitiss, hy meane of mechanism.

Touch is the most simple, and is generally employed. The machine shown at Fig. 4, operates partly hy hoth msthods, hut ths other implements are all on tho touch principls.

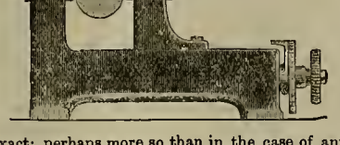
I will first speak of end contact, for Standard rods, and so on. This was prnposed hy Sir Joseph Whitworth, ahont the year 1850. He contended, and proved, teo, that the greatest prscision in dsfining a length, was hetwsen ths two ends of a bar, its length to he dstermined and measnred by contact or touch. I do not think thers was anything new in the method proposed, hecause the mster estahlished hy decres 1795 was a har with end contact.

Sir Joseph's invention consisted in new and more accurats mechanisms for testing or comparing lengths. He had made in his works in Manchestsr in 1851, a small machine, not unlike the ons shown ahove, only with more dstail, that wonld msasure or indicate the one one-millionth part of an inch.

Extraordinary as this may scem, it is strictly trus. Numerous public exhihitions of the machine havo hesn made sincs that time. I havs myself oftsn sesn and examined it, and am personally acquainted with the engineer, now a manags of a large works in England, who made most particular parts of the mschine. Familiar as I have hecn for ysars with dsvicss for contsct measurement, this sesms a difficult, but not impossihls attainment.

The fitting of the machine was, of course,

Fig. 6.



exact; perhaps more so than in the case of any mschanism sver before made; that was all. The tssts wers not mads hy placing pieces hetwesn points hy hand, as in the case of the machine here. A emall, thin plate of steel, called a "feeling piece," is employed. With the same appliances, and with the required scalcs for reading such minute quantitics, I think the present machine might indicate to the one one-hundred-thousandth part of an inch.

In some experiments tried with the Whitworth machine, a sensihle change could he detected in a har of mctal if the finger nail was allowed to touch it, so sensitive are metal rods to changes of temperature.

Comparisons are made hy touch, hut msasurements must he read hy sight. It is easy to distinguish minute differences hy touch, hut to tell how much these differences are, or their valne, ae it ie called, measuring scales are required.

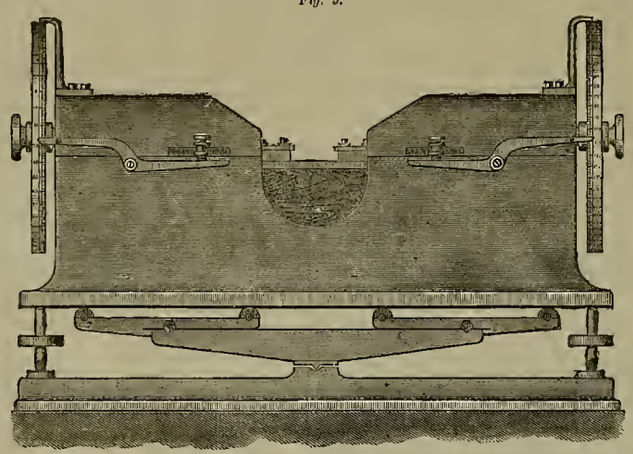
In the Standard machine at Philadelphia, shown in side elevation at Fig. 5, one of the wheels, 15 inches diameter, was marked with 1,000 divisions. In eome of the higher-class machines for shop use, we divide to 500 divisions,

Figs. 6 and 7 show calipsring machines of the form commonly employed in enginssring estahlishmsnts.

I think ths apparatns employsd at Washington for comparing two things, the Standard yard or metcr, for sxample, is perhaps the most perfsct ever devissd, and is extrsmsly simpls. A small, flat mirror is mounted on an axis, so as to swing for a short distance. Rods to hs compared are so plscsd as to coms in contact with this mirror, and if they hs longer or shorter, ths mirror is turned on its sxis accordingly. From ths fsce of this mirror, a ray of reflsctsd light nesrly 30 ft. long falls on a graduatsd arc, so ths least change is magnifisd hundreds or thousands of times, so as to hs sasily sesn and read.

Anyone can try and sxperiment in multiplying movement in this way, by holding a flat mirror in the snnlight and throwing the reflection on a distant wall. The slightest movement

Fig. 5.



of the mirror will causs a grsat movemsnt of ths rays of reflected light. The light is, in effect, a long postsrior index.

A common clock may ssrve as an sxampls of another means to magnify motion in minnts measursmsnts. Suppose that in a sevsn-day clock the wsight descends fonr fest in a wesk of 168 hours, and that the minute hand is six inches long. The point of the minuts hand will movs in a week 252 ft., whils the wsight moves four ft., ths proportion hsing as 63 to 1; that is, ons inch of movsmsnt of the wsight would produce five ft. one inch of movement at the point of the minuts hand.

Supposs the same clock to have a second hand two inches leng, that would move in a week 5,040 ft., or 1260 timss as far as the weight. When the weight descended one inch, the secoud hand would move 105 ft. Now, such a clock would he a very correct measuring machine, and one of surprising sensitiveness, if there were some way provided for determining the distancs moved hy the weight. If, for example, the second hand wers moved 1¼ inches, the weight would descsnd one ons-thousandth of an inch.

At first thought, it seems that a measuring machine could thus he made, and he at the same time cheap and simple; hut it would not do at all for measuring. Minute differences could he shown or felt, hut measuring is quite another matter. The clock weight, in the example assumed, might descend one-thonsandth of an inch during the first 1¼ inches the second hand was moved, hut it might not descend the same for the next 1¼ inches, it would not do so indeed hecause trains of cog wheels such as are employed in reducing clock motions, or indeed any cog gearing would not do to measure with. Screwe are generally regarded as an accurate meane of producing uniform motion, and are employed in all measuring machines I have seen, hut suoh ecrews are far from true.

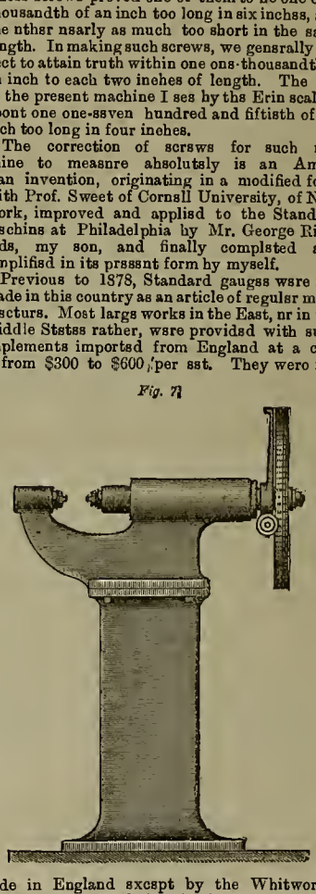
The longest measuring range attempted by Sir Jossph Whitworth is, I helieve, two inches.

I have paid to Sir Joseph Whitworth & Co. more than $25 each for screws one inch in diameter and sevsn inches long, made with all possihle care and guarantsed to he Standard. Thess screws proved one of them to he one onsthousandth of an inch too long in six inchss, and the nthsr nsarly as much too short in the same length. In making such screws, we gensrally expect to attain truth within one ons-thousandth of an inch to each two inches of length. The one in the present machine I ses hy ths Erin scale is abont one one-ssven hundred and fiftisth of an inch too long in four inches.

The correction of scrsws for such maohine to measnre ahsolutsly is an American invention, originating in a modified form with Prof. Sweet of Cornsll University, of New York, improved and applisd to the Standard mschins at Philadelphia hy Mr. George Richards, my son, and finally complsted and simplifisd in its prsssnt form hy myself.

Previous to 1878, Standard gaugss wsre not made in this country as an article of regulsr manufscturs. Most largs works in the East, nr in the Middle Ststss rather, wsre providsd with such implements importsd from England at a cost of from $300 to $600 per sst. They were not

Fig. 7.



made in England sxcspt by the Whitworth Co., so you may well imagine it was a business of some importancs to that company. In 1878 and 1879, tho manufacture was hegun in Philadelphia, or rathsr the first accurate implsmsnts were made, hecause the business was commenced in 1862, or soonsr.

In a paper read hefore the Franklin Institute in 1879, I gave a detailsd account of the origin and prngress of this difficult mannfacture. This paper, with drawings of some of ths machinss employed, has rccently heen puhlished here in San Francisco, and is furnished free to applicants hy ths San Francisco Tool Co.

[Concluded.]

Mining Profits.—As an illnstration of the profits to he derived from mining sntsrprises and invsstmcnts, take the Con. Virginia, of Nsvada (eilver), which has paid $42,930,000 in dividends. The Calumet and Hecla (copper), has paid $19,850,000 in dividends; the Cantral (copper), $1,560,000; the Homestake (gold), 1,110,000; the Idaho, $3,024,000; the Northern Belle; $1,987,500; the Plumas, $1,194,840; the Quincy, $2,710,000; Sierra Buttes, $1,160,000; Standard, $3,000,000; and the Western, $1,200,000, not to mention the hundreds of other companies that have divided enormous sums amongst stockholders, and, more than large and regular dividends; in many instances the etock has doubled, trohled and qnadrnpled in valne.

Reports from the recently discovered mines near Palisade are discouraging. It was said that the ore was as rich ae that found in Safford district, and the prospecte fully as good as those of Safford, hut the leader saye several samples essayed in Eureka failed to pan out worth a cent, although the rock had every indication of carrying metal.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Butte City and Mines.—Montana.

Winter Coming On.

EDITORS PRESS:—Since my last writing, matters and things in this city and vicinity have remained much the same as at that date. Admonished by the near approach of winter the great activity in getting out lumber, providing fuel and erecting buildings has increased, though the immigration has, for the same reason, been about stopped. Meantime a good many have left, and more will leave before the extreme cold weather sets in, thus further relieving the stringency of the situation. These deep snows and long winters constitute the one draw-back to Montana. But the disadvantages growing out of them will be measurably obviated when the principal mining centers come to be connected with the outside world by means of railroads, as they soon will be.

The Early Extension of the Utah and Northern Road

To this point may now be considered certain, the efforts being made on the part of our citizens in furtherance of that end, promising to be crowned with success. The company building that road has shown a commendable spirit of enterprise from the first, having commenced the work and pushed it north from Ogden, its starting point, at a time when the resources of this northern country, though pretty well known to be large, had as yet been but little developed. Then the Wood River mines had not been discovered, while the wealth of the still more important mines about Butte remained in good part to be established—districts that will become the two great business feeders of the road.

The track of the Utah & Northern, a narrow-gange road, has already been laid down for a distance of over 250 miles, and will no doubt be hereafter rapidly extended this way. Some of our merchants do not very warmly espouse the cause of the railroad, fearing it will reduce the price of goods and promote competition. But the community in general regard this, of course, as a short-sighted view, well knowing that the road, by cheapening freights and facilitating travel, will greatly advance every other interest.

The Mining Outlook.

With every week's work the mines here show marked improvement, leaving little doubt but Butte will in the course of a few years become one of the greatest mining centers west of the Rocky mountains. The trouble at this moment is that we have more ore than we can possibly handle with our comparatively few reduction works and limited facilities for transportation. So abundant and so easy of extraction are the ores here that the stock on hand will for a long time most likely be greatly in advance of the means for disposing of it. If our means for treating the ore on the ground were doubled and we had added thereto the advantages of shipment by rail we could still without much strain meet all new demands on the resources of our mines.

Work of the Week.

A few remarks on the present condition and aspect of affairs will sufficiently indicate the progress made here in a general way since my last writing.

On the Moulton, exploratory work and ore extraction have been pushed with accustomed vigor. A heavy flow of water has been struck on the 300 level, indicating the presence of a strong and fertile fissure at that point. No stoping has yet been done here, nor can there be any until the large pumping engine, now on the ground, is gotten in place. Meantime, about 25 tons of first-class ore are being daily raised, a quantity that will be doubled as soon as the 400-ft. crosscut taps the middle vein. The site for the new steam hoist for the west shaft, now on the ground, is being excavated. This mine is coming rapidly to the front, and may perhaps be already considered the most promising in the district.

Of other mines here, it may be remarked, the Alice is taking out and milling her accustomed quota of ore and preparing to declare her usual monthly dividend, a condition of things that will probably be continued for many a month to come.

The Lexington, Stivens, Bell, Gagnon, Original, Acquisition, and a score of other mines of scarcely less note, are all being actively worked, and the majority of them yielding more or less high-grade ore.

The consolidation of the Burnett, Mountain and Buffalo claims, mentioned in my last letter, has just been consummated in the election of the following Directory, viz.: Jas. A. Talbot, President; W. A. Collingwood, Vice-President; R. S. Jones, Treasurer; H. S. Clark, Secretary; Prof. J. E. Clayton, Consulting Engineer. This property has been capitalized at $4,000,000, a large but not an excessive sum in view of its great magnitude and unmistakable value. One-half of the entire stock is to be sold to raise a working capital, thus insuring ample means for opening and equipping the mines, and guaranteeing shareholders against future assessments. The outlook for this company is every way encouraging.

Among the successful men in Butte are to be numbered several old and well-known Californians, some of whom have acquired large and valuable interests, both in the mines and in city property here. It will gratify thousands on the Pacific coast to learn that among those so prospered is Prof. J. E. Clayton, the well-known mining expert and engineer who, coming here early in the capacity of adviser to the Walker Bros., the Salt Lake City millionaires, secured large interests in some of the leading mines, and is now in a fair way of becoming a very rich man.

NEW MONTANA.

Oct. 14, 1881.

Camp Glencoe, Calaveras.

EDITORS PRESS:—This venerable quartz mining camp is still the center of attaction in this part of Calaveras county. Even the U. S. mail stage is now rushed through at the rate of almost three miles per hour. Daily strangers are not a curiosity any more. The larger number are men seeking work. Six boarding houses are crowded. Accommodation in the way of lodging is deficient and when obtained not very desirable.

The Valentine Co. and Norwich Co. are at present the principal fountains of circulating ducats.

The Norwich Co. supply their 18-stamp mill from the stopes of the Norwich mine. This company are also erecting steam power hoisting machinery on the Montana, and have commenced work on the Monte Cristo. The mill is well provided with notices for the benefit of possible visitors that there is "Positively no Admittance."

The Valentine Co.'s new 20-stamp mill is a model of economy in milling. Cars dump the ore on iron-bar grates, the coarser ore descending to the rock-breaker, and the finer material into four of Hendy's challenge self-feeders. Two of Dodge's concentrators are in position on the floor below the batteries, the pulp being finally manipulated by a new style of sluice-concentrator. Here, also, the mysterious "no admittance" greets the visitor. The mill is driven by water power, but 10 stamps only are now in use, as the requisite quantity of water cannot be had for the present. The ore is being extracted from the lower tunnel, but a "no admittance" and a corpulent padlock limited the view of your inquisitive correspondent.

The Mexican mine is still yielding rich specimen ore. The owners intend to work on a larger scale hereafter, as soon as the backs now accessible have been stoped.

The genial owner of the "Kaiser William" mine, Mr. Enright, has at last reached ore in his tunnel which is said to be worth $100 per ton. Mr. Enright (a disciple of our worthy State Mineralogist, Mr. Hanks, I believe) has not alone met all expenses from his own pocket but also develops his muscle and scientific attainments in a thorough, practical manner.

The Foot & Thompson mine near Upper Rich Gulch, has been recently sold to Professor Blake on account of Eastern parties. The vein trends northwest, the mine being near and at right angles with the Mokelumne river, giving the unusual advantage to develope extensively by tunneling on the vein. The property produced enormously years ago, but was eventually involved in litigation until Mr. H. Atwood received a United States patent for the mine. The old mill near the river, which pounded out hundreds of thousands of dollars, finally yielded fine pickings for a company of Chinamen who washed up some $80,000 worth of amalgam which had been lost in milling. Of course John kept the secret until the bonanza was exhausted, but the amount of retorted amalgam sold was sufficient proof.

S.

Calaveras Co., Cal., Oct. 21, 1881.

Mining on the Klamath.

Live and Steady-Going Miners.

Placer operations in this section of Siskiyou county, do not, as in most other parts of California, abate with the advance, and finally cease with the consummation of the dry season. On the contrary, while the most of our large hydraulic companies run steadily through the summer and autumn, the river-bed miners find the latter their most busy season. Thus it comes that even this late in the year the majority of our miners are hard at work, and much gold is being taken out, rendering business of all kinds easy, and preserving it from the fluctuations elsewhere common. And in this connection, it may be observed that some of the houses in this place do a large and varied business. The firm of Camp & Titus, for instance, sell something like $200,000 worth of goods in the course of the year, there being several other traders who dispose of quite a large amount of goods.

The Good Points in our Mines.

Among our nearly uninterrmitting hydraulic mines are the Richardson, the Furguson and Frazier, and various claims about Wingate Hill and Bunker Hill, farther down the river, the Woods, Mucamuc, Chiua Creek, and many others managing to run for a good part of the year. Besides these long working seasons our miners are little interrupted by stopping to run powder drifts, blow up the gravel banks, remove bowlders, etc., there being little of this sort of work here to be done. If capitalists would come up and take a look at the hydraulic mines along the Klamath, they would see a very different state of things from that presented in the counties farther south—no long bedrock tunnels to be run; no hard cement to fight or barren stuff to be removed, rich gravel and plenty of it, an abundance of water easily introduced on the mines and above all no trouble about the debris which runs away into the ocean and harms no one. Conditions that ought to recommend our mines to investors, if they are looking for mines of this kind or if indeed they care to invest in mines at all, for there can be none safer or more profitable than these along the Klamath.

The Wing-Dammers

Are this year reaping a rich harvest in the bed of the Klamath, from which, it is probable, there will be more gold taken out before the season closes than during any previous year. What promises to give new interest and importance to this branch of mining is the fact that it will soon come to be prosecuted by means of tunnels driven under the river bed, or by shafts sunk down to it instead of by wing-damming, the method now in vogue. Should the new plan prove successful it would enable the miner to carry on his work continuously, or nearly so, instead of being forced to suspend it for three-fourths of the year, as at present, besides bringing to him other great gains. Working the bed of the Klamath and Scott rivers though actively carried on for nearly 30 years, is a business that has still a long life before it.

OLD SETTLER.

Happy Camp, Cal., Oct. 20, 1881.

The Hite Mine.

To pen an article giving to this great mine an adequate amount of what it justly merits, says the Mariposa *Gazette*, is almost impracticable for us to reach. Ever since its discovery and location by Mr. Hite, nearly 20 years ago, we have been intimate with the premises, having watched its development and production with great anxiety and interest, with a view to its becoming one of the chief tributaries from which this county was to derive a source of benefit above all others of a mining nature. Our prophecies at the commencement, were that time would develop the fact that this would be one of the best, and rank among the first-class and permanent mines of the Pacific coast. Nearly 20 years have elapsed since work upon this mine first commenced, and notwithstanding the labor of development has been vigorously pushed during that time by Mr. Hite, and a great amount of gold extracted therefrom, the mine at the present, comparatively speaking, is in its primitive state—undeveloped and unexplored. With all the vigor at the command of capital and best management, it will require another 20 years to fathom and develop the resources of this great mine, which will exist and pass into future generations with an increased value above all estimates that can well be calculated at this period of time. The present status of the situation of things at the mine, which is under the control of the "Hite Gold Quartz Crushing Co." a corporation of New York, and managed by Mr. A. J. Bothwell, shows an immence amount of progress, and the Cove is the scene of great activity.

The company has already completed several important improvements, consisting in putting in one of the largest compressors ever made, rebuilding the dam, repairing the flume, putting in new plates and reconstructing the machinery of the mill, and other improvements belonging to the mine and mill generally. In the mine, the work of opening up new levels is to be pushed forward as rapidly and vigorously as improved machinery will permit. A compressor engine has been placed at the lower dam, and a mile of four-inch pipe has been laid to conduct the air to the pump, hoisting engines and power drills in the mine. A large compartment shaft has been sunk below the tunnel level, and will be pushed down without interruption to the depth of 500 ft; levels will be run every 100 ft. The shaft is going down in the west ore body, and all rock taken out in sinking is sent to the mill. The mill has been thoroughly overhauled and repaired, and is now one of the best 40-stamp mills on the Pacific coast. The South Merced river furnishes power to run the mill and compressor. The dams and flumes have just been reinstated for the winter's run. The superintendent expects to complete nearly all his preparatory work during the coming month; after which the development work in the mine will advance with great rapidity. The public here who have known the Hite mine for many years as the best gold producer in the country, expect great results from the mine when worked by improved machinery under a vigorous and capable management.

Of the States and Territories of the Union, California stands No. 1 in the production of gold, quicksilver, sheep, vineyards and barley. She stands No. 5 in cattle; No. 6 in silver and wheat; No. 7 in silk goods; No. 8 in milch cows; No. 11 in coal and hay; No. 13 in potatoes; No. 14 in miles of railway; No. 15 in horses; No. 16 in oats; No. 17 in mules; No. 19 in hogs; No. 21 in iron and steel; No. 28 in corn. Colorado stands No. 1 in silver production, and Nevada stands No. 2 in silver and gold production.

Consolidated Virginia.

Interesting Facts in Its History.

The stock of the Consolidated Virginia mining company first appeared in the San Francisco Stock Boards in March, 1870. During that month it sold between $10 to $17—neither higher nor lower. In July of the same year it sold for $1 per share, and remained at that figure until the fall of 1871; when it advanced to $16. It did not fall below that figure in 1872, and sold as high as $160, and it fluctuated between that sum and $42 during the year 1872.

It was in 1874 that the excitement began, and in that year it sold for $610 per share. In January, 1875, however, it reached its highest figure—$700; California at the same time sold for $780. The capital stock of each company at the time of the two highest prices was 108,000 shares. The companies now have a capital stock of 540,000 shares each.

The Consolidated Virginia mine passed into the present management January 11, 1872. For five years, from 1867 to 1872, a company worked the ground all the time, expending $161,340.41 upon the property without realizing $1 in return. At last it was forced to give way. The new and present management expended $277,150.12 before it yielded them anything. It was a stubborn fight against the heat and barren porphyry—a steady pouring out of gold on a hope, which continued eight years and which would have been abandoned in any other country but this, and by any other class of men in the world except Nevada miners. The last assessment on Consolidated Virginia, levied June 11, 1873, was $3 per share. It was the fifteenth time the stockholders had been called on to pay for the work of exploration and brought the aggregate amount of assessments levied, up to $111,200.

The company paid 53 dividends, aggregating $42,930,000, the last dividend—fifty cents per share—being disbursed in August, 1880. The dividends of Consolidated Virginia and California aggregate $74,250,000.

The Valley of Death.

The Fate of Immigrants on its Burning Sands.

The Valley of Death, a spot almost as terrible as the prophet's valley of dry bones, lies just north of the old Mormon road to California—a region 30 miles long by 30 broad, and surrounded, except at two points, by inaccessible mountains. It is totally devoid of water and vegetation, and the shadow of a bird or wild beast never darkens its white, glaring sands. The Kansas Pacific railroad engineers discovered it, and some papers, which show the fate of the "lost Montgomery train," which came south from Salt Lake in 1850, guided by a Mormon. When near Death valley, some came to the conclusion that the Mormon knew nothing of the country, so they appointed one of their number a leader, and broke off from their party. The leader turned due west, and so, with the people and wagons and the flocks, he traveled three days, and then descended into the broad valley, whose treacherous mirage promised water. They reached the center, but only the white sands, bounded by scorching peaks, met their gaze. And around the valley they wandered, and one by one the men died, and the panting flocks stretched. themselves in death under the hot sun. The children, crying for water, died at their mother's breasts, and with swollen tongues and burning vitals, the mothers followed. Wagon after wagon was abandoned, and strong men tottered and raved and died. After a week's wandering, a dozen survivors found some water in the hollow of a mountain. It lasted but a short time, when all perished but two, who escaped out of the valley and followed the trail of their former companions. Eighty-seven families, with hundreds of animals, perished here, and now, after 22 years, the wagons stand still complete, the iron works and tires are bright, and the shriveled skeletons lie side by side.

PROGRESS OF THE ENGLISH CHANNEL TUNNEL.—A French journal announces the near completion of the first sections on both sides of the submarine tunnel between England and France. On the French side 1,800 meters have been tunneled, and on the English side 1,600 meters, in all over two miles, or about one-tenth of the entire distance. It is proposed at the end of November, to run some experimental trains in the two sections, so as to judge what effect, if any, is produced from the concussion caused by the running trains.

THE NEW TAY BRIDGE.—The total length of the new Tay bridge in Scotland, which will take the place of the one which went down with such terrible loss of life, will be about 10,000 ft., or about two miles. The bridge will be built strong enough to resist more than twice the force of the hardest gale that may sweep against it. The wind-pressure is placed at 21 lbs. per square foot, and allowance is made for 56 lbs.

EARLY SNOW.—On the 13th inst., the snow was flying quite lively for an hour or two as low down in the foothills of the Sierra as Grass Valley.

MECHANICAL PROGRESS.

Mechanical Applications of Electricity.

As was anticipated, the great electrical exposition of Paris is doing a good deal to show the useful capacities of electricity. It is drawing attention to what is inquired for—the motive powor of the future. Steam has done a vast deal for the world; it has heen a great promoter of civilization. It revolutionized manufacturing and transportation. What it has accomplished was scarcely coasidered possible when it was first imporfoctly harnessed to a river vessel. Its progress was rapid and wonderful, aad commerce and civilization have sung pæons to its magaificent advantages.

To-day, says an. exchange, tho world is looking heyond steam. Another motor-power is asked for—is expected. Steam doss not now mest the wants of the age; it spends too much forco for the rosults attainod. It is hecoming costly, and has used up the wood, and is fast consnming the coal that will be wanted for houschold heating purposes. Quicksr travel, less expenss, is tho demaud for the times. Will the demand be met? Ths need is a prophecy that tho thing will he found, for in the march of events, when civilization has needed somsthing moro, it has come. The idea that the new motor is to come from electricty has taken possession of the scientific mind, which therefors is looking in that direction.

But notwithstanding, says another exchaugs, the application of electricity for many practical purposes has grown so rapidly within the last few years, and the success in some fislds has heen so startling and has suggested such possihilities that the general public takes an eager interest in all that rslates to it, and many busy and ingcaious inventors and engineers are working in its varions specialties, and appealing to the masses for aid, they allowed themselves, or others for them, to speak in a sensational style that has done much injury to the cause of real progress; snd it is with much satisfaotion thst we notice a tendency in a hetter and safer direction. Calm examination and ths presentation of specific data are commencing to supersedo the glowiag generalities which often sonnded very ncarly like passages from one of Jules Verne'e works. The public has learned that a very meritorious invention may he unscrnpulously handled hy speculators, and the early enthusiasm has given way to a desire to obtain more and hetter information ou such matters.

The electrical exhibition at Paris is contrihuting much toward that end, and it gives evidence, too, of the efforts making to apply electricity to various departments of mining and metallurgy. At the present early stage of progress, many points are not thoroughly understood, and there ie noticeahlc the absence of cooperation between the electrician and the eagineer; and before the one has fully apprcciated the requirements of the other, and has command of the meane at his disposal, errors will he made, and the new inventions will not have assumed a practical shape. We hear of electrical hammers, rock-drills, elevators, tramways and processes, and it is likely that they will in the near future claim and receive much attention. While there is much that gives promise of ultimate success, and developments onght to he closely watched, it should not he forgotten that all theso appliances will have to go through a period in which means are adapted to the ends. As prohably capahle of adding valuable methode to those now in use for the ntilization of our mineral wealth, engineers will welcome the electricians, hut they should move forward with the caution that past experience has taught them to he necessary.

DAMASCUS STEEL.—Perhaps the hest method which has ever heen discovered for tempering steel, resulting in hardness, toughness, and elasticity combined, is that followed in hardening the hlades of the famous Damascus sworde. The furnsce in which the hlades were heated was constructed with a horizontal slit hy which a current of cold air from the outside entered. This slit was always placed on the north side of the furnace, and was provided on the outside witb a flat funnel-shaped attachment hy which the wind was concentrated and conducted into the slit. The operation of tempering the hlades was only performed on those days of winter when a cold etrong north wind prevailed. The eword-hlade when hright red hot was lifted ont of the fire snd keptin front of this slit and hy this msans was gradually cooled in the draft of air. It acquired the proper degree of temper at the single operation.

HOLLOW STEEL SHAFTS FOR STEAMSHIPS.—Among the recent improvements introduced in Eogland in huilding large steamships, are hollow steel shafts, which are chiefly manufactured hy Sir Joseph Whitworth & Co. On this system a 10-inch shaft has a hole 4 inches in diameter, reducing the weight 16%, while the strength is only diminished hy 2.56%. With a 5-inch central hole these figures would he 25% and 4.25% respectively.

STEEL IN MALLEABLE CASTINGS.—The nse of steel as an addition to the white pig usod in making malleahle castings is increasing ahroad. Scrap ateel has hecn largely used in this country for some time.

Steam Boiler Notes.

A foreign correspondent of the *Scientific American* wishes to know why locomotive hoilers work satisfactorily witb so much lcss steam room per horse power than is nsually found in marine hoilers. He cites good English practice to sbow that fully tbree-fourths of a cubic foot of steam room is allowed per indicated horse power in marine boilers, while only one-eighth to one-twelfth of a cuhic foot is allowed in locomotive hoilsrs, and asks—To what sball the steam room be proportioned, if not to the indioated horse power?

In the above the journal named roplies as follows: The answer to tho first part of the inquiry is,—The greater pressure relatively to ths power developed in the locomotive. But the snhjact does not seem to admit of such categorical treatment as our correspondent ssems to indicate hy the tone of the qnery. Perhaps an empirical rule might he made from a sufficient nnmher of experimants, embracing most of the conditions of modern practice, hut the factors of the problem include everythiag that affects tho rate of evaporation and ths free escape of the steam from the surface of the hoiler water and the steam prssnre. Ths efficiency of the heating surfaces, the ratio of grate to heating surface, the rate of comhustion, ths circnlation of the water, the quantity of water and its depth upon a nnit of heatiag surface, the surface area from which the steam sscapes into the steam space, the pressure upon that surfacs relatively to the power developed hy the engine; and inasmuch as the nnmher and volume of the cylinder charges for cut-off engines are determined, in some degrse, hy ths grade of expansion for a given powor, the point of cutting off ontsrs with the other numerous factors into the problem.

TEMPER OF STEEL.—The temper of steel is due to the chemical union of the iron with ths carhon. At low tamperaturss this union takes plsce only a slight degrce, and hence in soft steel we have the carhon kespiog aloof from the iron; but as the temperature is raised the combination is furthered, until in the case of grsy or glass hard steel we havs really a kind of diamond alloyed with iron. Sudden cooling is necessary to fix the combination; for in slow cooling the carhon separates out again from the iron. This view is supported hy a variety of facts; Mr. Stroth, for example, having ohserved that when an electric spark passes hetween two iron contact pieces and fuses them, the fused part hecomes diamond hard and will scratch a file. Recent researches hy Mr. T. W. Hogg have also led him to a similar conclusion—namely, the tempsr of steel is due to the presence of sn unstahle compound of iron and carhon. The color of the surface of tempered steel depends on the temperatnre, and is dne to the thickness of the film or skin of oxide; the hlue film signifying a higher temperature than the yellow, as well as a thicker coating. In this connection Prof. Hughes has demonstrated that the electric resistance of the film increases with the temperature.

ROLLING OF WIRE AND FINE IRON.—Mr. Julius Schmidt (Schmidt Bros.), of Schwelm, Westphalis, has recently proposed the cold rolling of wire and fine iron hy means of small rollers with eemi-hexagonal grooves, forming a hexagonal section. The application of the hexagonal rollers has the advantage, he says, that the wire or fine iron is always under a central pressure, the structure of the metal will not alter, and the formation of seams is avoided. Each pair of rollings is carricd in little hsarings fixed on a standard. All standards rest on a foundation plate, which at the samo time carries the main standards on which the plunger hlocks for the driving shafts are fixed. The latter serve for the motion of the rollers; the train of wheels is so arranged as to ohtain such speed and direction of motion that the wire will pass through the rollers first one way and the other, or alternately forward and hackward.

AMERICAN CARS ON BRITISH RAILWAYS.—Eacouraged hy the success which has attended the introduction of dining-room cars on the Great Northern railway, the Midland railway company have decided to follow in the same direction. They intend to place a dining-room car on all their express trains rnaning hetween London, Manchester and Liverpool. These cars are to he made hy the Pullman Palace Car Co. The same company are making several new palace cars for the London, Brighton and South Coast railway. Since the Brighton tragedy, the demande made upon the Pullman car accommodation have heen so great as to he in excess of what is at present at the disposal of the company. The directors have consequently decided to run a train cach way every day, to he composed entirely of Pullman cars.—*London Times.*

HEAVY PLATE ROLLING.—In Sheffield, Eugland, a few weeks since, the apectacle was witnessed hy a number of distinguised visitors, of rolling a huge ateel-faced plate for a government war steamer now building. The process, known as the Ellis patent, was satisfactorily completed in a quarter of an hour. The weight of the plate was 30 tons 16 cwt., and the length 10 ft. 4½ inches; hreadth, 8 ft. 9 inches; and thickness, 19 inches. Afterward, the visitors witnessed the flanging of marine hoiler ends by hydraulic pressure in one operation.

SCIENTIFIC PROGRESS.

Interesting Mineral Discoveries in Arizona.

Prof. B. Silliman records in the *American Journal of Science*, the discovery of vanadinits and other crystalline salts of lead, of great heauty of color and perfection of form, in the Territory of Arizona. Some of the varieties—crocoite, a chromate of lead, and vanquilinite, a varisty containing copper—have never hefore heen found in North Amorica. Vanadinite, chloride of lead and vanadium, hitherto a rare species, promise now to be comparatively ahundant in the silver district in Yuma county and other localities.

It is fonnd in veins of quartz which lie hetween footwalls of granite and hanging walls of porphyry, the latter heing similar to the usual associates of silver ore the world over. The quartz veins have also other salts of lead and argentiferous galena, hut no gold. Vanadinito occurs in the Hamburg, Red Cloud and Princess miaes. That in the Hamhurg is the hest. The crystals are small and highly lustrous, varying in color from deep orange-red to reddish yellow and hrown.

In Red Cloud they are a rich flame color, and are fonnd in rathar confused masses. In Princess mine ocenr slender crystals of a hrilliant red color hedded in white calcite. They are very perfect in form, and have heen mistaken for chromate of lead.

Other rare speoies are found in the Vulture district, in the vicinity of the Vulture mine, while at Collateral mine, about 25 miles northeast of Vulture, is the most interesting locality. The vein is ahont 4½ ft. wide in soft gray talcose rook. About one-half of the thickness of the vein is qnartz, stained green with chrysocolla and chocolate hrown with ground mass which contains vanadium. The colored masses all give strong reaction for vanadic acid.

The whole soft mass of the vein reacts for vanadic acid, and specimens of rare heauty are found in the cleavage fragments of ths calcite.

Among the ores found in this "Collateral" minc is a mineral which may prove to he descloizite. The tests of it indicate the presence of vanadium, lead, copper, manganeese and zinc, hut more specimens are needed to complcte the study of it.

A specimon is referred provisionally to the Volhorthite species.

This mineral has a green color, and contains copper, lime, and vanadic acid. It was named after Volborth, its diecoverer; hut tho specimen discovered in "Collateral" mine may turn out to he a new species.

A mineral like Domeyko's *chileite*, but not a clay-like mineral, which yields a glohule of lead containing a nucleus of copper, occurs both in this miue and in the "Chromate," and something similar is found in the "Phœnix" mine. The Montezuma lead mine ahounds in vanadinite in the form of hexagonal prisms.

What may prove to he *mottramite* has heen found at the "Frenchman's" mine. Wulfenite, molyhdate of lead, which does not contain vanadic acid, has heen found in crystals of rare heauty in "Red Cloud" mine, as well as the vanadinite hsfore mentioned. It is also found in the "River" mine.

Three or four speoies of the *crocoite* group, that is, chromic acid with oxide of lead, occur in the "Collateral" and the "Chromate" veins, hut as yet it has not heen found well crystallized. Before the study of these interesting localities can he complete a personal visit must he made hy a mineralogist to the mines, and sufficient material ohtained on the spot to allow of a chemical analysis.

THE most powerful artificial light in the world has just heen constructed hy Messrs. Chance Bros. & Co. at Smethwick, near Bermingham, Eng., for the South Head lighthouse, near Sydney, New South Wales. It is called a first order, dioptric, revolving light, with the electric arc. The lamp has a special arrangement of prisms for securing vertical divergence of the heam. It is over six ft. in diameter, and the hight is ahout nine ft., and it is said to be the first time such dimensions have heen applied to illumination hy the electric arc. The lamp has a power of about 12,000 candles in the focus of light, and the merging heam has a luminous intensity exceeding 12,000,000 candles. The light will give flashes aronnd half the horizon at intervals of a minute, and will make a complete revolution every 16 minutes. On an aversge, the light will he visihle a distance of 40 to 50 miles. At an exhihition of its power recently given at Smethwick, the light was so intense that it could hardly he endured hy the naked eye.

SUPPOSED NEW SPECIES OF HORSE.—M. Poliakoff, the distinguished Russian naturalist, has examined a horso presented hy Col. Prejvalsky to the St. Petershurg Academy, and decides it to be a new species, which he has named Equus Prejvalekii. It appears that the new representative of the family of undivided-hoofed mammals is in some respects intermediate hetween the domestic horse and the wild ass, but it differa from the asinine genus, in having four callosities, one on each leg. In the form of akull, absence of dorsal stripe and other particnlara, it resemhlea the horse. Thia newly recorded animal is indigenoue to plains and deserts of Central Asia, and has not hitherto fallen under the dominion of man,

CASTINGS OF DELICATE NATURAL OBJECTS.—Ths following process is recommen led hy Ahhas for prodncing metallic castings of flowers, leaves, insects, etc.: The object, a dead beetle, for example, is first arranged in a natnral position, aad the feet are connected with an oval rim of wax. It is then fixed in tho center of a paper or wooden hox hy means of picces of fine wire, so that it is perfectly free, and thicker wires are run from the sides of the hox to tho ohject, which suhsequently serve to form air channels in tho mold hy their removal. A wooden stick, tapering toward the hottom, is placed upon ths back of the insect to produce a runner for casting. The box is then filled up with a paste of three parts of plaster of Paris and ons of brick dnst, made up with a solution of alum and ssl ammoniac. It is also well to first hrush the object with this paste to prevent the formation of air hubhles. After tho mold thus formed hss set, the object is removed from the interior hy first reducing it to ashes. It is therefore dried slowly, and finally heated gradually to a red heat, and then allowed to cool slowly to prsvent the formation of flaws or cracks. The ashes are removed hy pouring mercury into the cold mold and shaking it thoroughly hefore pouring it out, aod repeating this operation several times. The thicker wirca aro then drawn out, and the mold needs simply to be thoroughly heated before it is filled with metal, in order that tho lattar may flow into all portions of it. After it has become cold it is softened and carefully broken away from the castings.

THE COMET AS SEEN FROM A BALLOON.—M de Fonvielle has described the appearance of the great comst as seen from a balloon on tho occasion of his recent ascent at midnight. Tho hrightness of the comet increased as the balloon ascended, this increase of hrilliancy heing very marked. The tail appearsd a little loager thsn when seen from the earth's surface, hut most remarkahle was the manner in which it terminated, for it was cut off straight, as if a line were drawn over it horizontally with a rulor. The appearance of the tail was as if prodnced hy myriads of largs stones taaveling in planetary space independently of the comet, and having no other connection with it than that of heing temporarily lighted hy the rays which its atmosphere had canssd to deviate, more or lcss, from their natural course. This multitude of fragments of other worlds would, therefore, produce the same effect as dust lighted by a ray of sunlight admitted into a dark room through a crevice. M. de Fonvielle expounds this theory at some length. He also insists upon the importance of hallooning in astronomic investigations.

PROGRESS IN PRACTICAL SCIENCE.—Tbe astonishing speed with which revolutions in practical science succeed each other in the present age is indicated hy the fact that already eminent scientific men have hegun to predict the disappearance of the steam engine, whose rise scarcely dates hack heyond the memories of our own generation. At a recent meeting of the British Association, some of the leading members argued that the steam engine has already had its day, and will be superseded hy some motor which does not expend so much force with so little result. What that power shall be, the distinguished scientists do not seem to have predicted, although many eyes are turned toward electricity as the probable motor of the future. We are not yet prepared, however, to relegate steam power to ohlivion, although it is admitted that in its production there is an absolute loss of much the largest percentage of the efficiency of the fuel employed.

A REMARKABLE COMET.—Prof. Klein, an astronomical ohserver at St. Louis, Ky., makes the followiag statement, under date of Octoher 18th: "I have, for several weeks past, noticed a singular phenomenon in the heavens, in the shape of a double comet, or comets, attended with nine smaller ones all in a circle, closely resemhling one of Saturn's rings. They all appear to he connected, as they move in the same orhit, and the larger of the double comets will at regular intervals eclipse the smaller one, and the little ones are on snch occasions lost sight of in the mist thus created. I have no doubt that this is the comet of 1845 and '46, supposed to have hesn destroyed. This, too, I helieve to be the comet of 1811, having a period of 35 years. Aside from this wonderful comet, or rather, 11 comets, there are five others now visible.

THE ELECTRIC LIGHT ON HEALTH.—Experiments by German scientists in ascertaining the peculiarities of the electric light, establish the fact that it is not only healthier than other methods of illumination in leaving the air purer, hut that it increases the power of the vision in some respects, especially in distinguishiag colors. Red, green, hlne and yellow are made much more distinct and marked under this light than hy daylight.

CONVERTING POWER OF THE POTATO.—Dr. J. B. Laws, of Rothamstead, Eagland, says that the potato possesses the property of converting a very much larger portion of the manure ingredients of the soil into human food than any of the cereal grain crops. For instance, to every hushel of wheat, ahout 100 lbs. of straw are grown, while the haulm of the potatoes when dry, is so light, that in experimenting we do not think it worth while to weigh it.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Germania, Oct. 18, $3,500; Hanauer, 18, $2,300; Horn Silver, 20, $7,500; Barbee & Walker, 20, $1,826; Horn Silver, 19, $7,500; Hanauer, 19, $2,200; Wood River, 19, $2,250; Germania, 20, $6,400; Stormont, 20, $3,080; Great Basin, 20, $4,100; Horn Silver, 22, $10,000; Mammoth, 20, $2,698; Barbee & Walker, 22, $2,880; Hanauer, 22, $2,200; Wood River, 22, $2,200; Alice, 23, $6,000; Horn Silver, 23, $10,000; Monitor M. & M. Co., Taylor district, from Oct. 20th to 25th, $7,242.97; Wai Wera Con., 18, $3,206; Christy, 23. $3,648; Bodie Tunnel, for October, $5,000; Western Belle, 17, $11,200; Northern Belle, 19, $5,350; Silver Belt, 21, $30,000.

CALISTOGIANS, firm in tho belief that there are large quantities of gold and silver in old Mount St. Hslena and vicinity, are not going to allow the embarrassments attending their recent sfforts to establish a quartz mill in their town, to end the enterprise. The *Calistogian* says a mill will be constructed there without delay, the machinery having already been ordered.

MINING SHAREHOLDERS' DIRECTORY.

The Mining Share Market.

The mining share market still remains dull and uninterssting. There is considerable hopo among many that a development will take place on the Comstock before long. Tho fact that John Mackay has started back here from Europe may have helped this impression.

There is talk of the hydraulic pumps at the Cholla-Norcross-Savage shaft being run here after hy natural pressure. It can he done hy using the water of the Virginia and Gold Hill Water Co. The matter is under discussion at present, and the only question of feasibility is the one of economy—whether it will he cheaper to huy water or firewood.

The first hulkhead in the drift leading from the Chollar-Norcross-Savage shaft into the Savage ground on the 2400 level has been removed. The mner portion was hlasted out, leaving the sides and top stand. As the entire hulkhead was of solid masonry, the remaining portion will add to the support of the ground, be side heing already in place in case it is found necessary to again hulkhead the drift. The flow of water was slight aud easily handled by the hydraulic pumps at the Combination shaft. This was owing to its having been drawn off hy the opening of a valve for tho hulkhead. The drift is found to he in good condition, aud it will not bs long hefore the second hulkhead is removed.

The total length of the drift is 721 ft., and the second bulkhead is pretty well in toward its face. From the face of the drift there remain 160 ft. to he run to meet the point where the main incline will strike the 2400 level, and the distance the incline yet has to go to reach said level is, according to the map, just 58 ft. Thus it will hs seen there is no very great amount of work to he done to make this very important connection.

The opening of this drift will not only cool the lower levels of the Savage, but will also he of great henefit to the Hale & Norcross, Chollar and Potosi as well.

Meetings and Elections.

Meadow Valley M. Co. Oct. 22: Directors, R. Wegener (President), George D. Edwards (Vice-President), W. W. Stetson, E. V. Joice, James McCora. The other officers elected were J. R. Duff, Superintendent; Bank of California, Treasurer; N. DeLaguna, Secretary.

Happy Valley Blue Gravel M. Co., Oct. 24: Directors, C. W. Banks, F. A. Berlin, N. Oray, S. Heydenfeldt and S. Foorman.

Silver Lick Con. M. Co., Oct. 24: Directors, Benj. Nealey (President), John J. Roach, Adolph Schander (Vice-Presidente), L A. Booth, John Sinclair. John Dcsbeck was elected Treasurer and J. W. Pew, Secretary.

Syndicate M. Co., Oct. 20: Directors, Charles H. Fish, George W. Hopkins, R. N. Gravcs, Robert Sherwood and H. M. Yerington. At a subsequent meeting of the Directora the following officers were elected: Chas. H. Fish, President; George W. Hopkins, Vice-President; H. M. Yerington, Treasurer; R. K. Colcard, Superintendent, and Jacob Statfeldt, Jr., Secretary.

SALT LAKE CITY is filling up with miners, who come to spend the winter months there.

Electricity for Power Underground.

On tbis coast the "pony boists," drills, etc., used in underground work in mines, aro generally run hy compressed air, led to these machines from air compressors on the surface. Steam is also usnd, but the compressed air is much preferahle for obvious reasons. Many persons have imagined that some day an application of electricity for the transmission of power would he devisnd, by means of which fans, etc., could he worked underground. We see that this idea has been put in practice in France. M. Mathet has submitted the details to the *Societe de l'Industrie Minerale*. The St. Claude shaft at Blanzy was sunk to the depth of 500 meters (1,640 ft.), for the purpose of searching for a faulted portion of the coal seams, and a heading was run from it across the strata. When this heading had reached a length of 400 meters (1,312 ft.), the ventilation became so poor that the temperature at the face rose to 95° Fahr., and the miners could work only for a few hours. After some ineffectual attempts to improve the ventilation hy simple means, it was decided to put in a fan 2.63 ft. in diameter, and run it by power transmitted hy electricity. An 8 to 10 horse power portahle engine was put up above ground, and, with a Gramme dynnmo-electric machine, was run at a speed of 1,200 revolutions per minute. The electric current thus generated was condncted by a cable, consisting of seven 0.044-inch copper wires, to a second Gramme machine coupled directly with the fan, and placed in the heading near the shaft. Running at 700 to 800, it required 2½ horse power, the useful effect heing at least 60%. The temperature at the face was only lowered 5°, hnt the men could work in eight-hour shifts. The return current was conducted from the underground machine hy an iron wire cahle. The cost of the whole plant is stated to have been only one-third of what a machine for delivering compressed air to the heading would have required.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

NEVADA CONCENTRATION CO.—Oct. 20. Capital stock, $5,000,000, divided into 500,000 shares. Directors—L. T. Lazure, Morris Hoeflisch, Oustave Frank, Willard G. Farwell, John Landers, Stephen G. Clark and John A. Bagley. The principal place of business will be in San Francisco.

RANSOME MANUFACTURING CO.—Oct. 26. Object: Manufacturing brick, stone and other material. Capital stock, $100,000, in 10,000 shares. Directors—E. L. Ransome, O. Alexander, C. E. Royce, A. A. Wigmore and H. Beveridge.

SIERRA MILLING, SMELTING & M. Co.—Oct 21.—Location, California. Capital stock, $10,000,000. Directors—L. Osborn, J. F. W. Veat, Robert O'Neill, W. J. Collins and Edwin Lewis.

QUINN M. Co.—Oct. 24.—Location, Nevada. Capital stock, $10,000,000. Directors—Josiah Howell, Walter M. Rockwell, W. W. Bausman, Emanuel Epstein and W. W. Stetson

MINING SUMMARY.

The following is mostly coudensed from journals published in tbe interior, in proximity to the minee mentioned.

CALIFORNIA.

AMADOR.

ETNA.—Cor. Amador *Sentinel*, Oct. 20: I made a flying visit a few daye ago to the Etna mine, which is situated on the bead of Grizzly gulch between the middle fork of the Cosumnes river and Spanish creek, 2 miles from where the latter empties into the river. It was discovered in 1879 by the Hite brethers while working placer diggings, and was called the Hite, Centeunial, or the Sulphurets mine, but ie now called the Etna. Spasmodic efforts bave been made to develop this mine during the past five years, but nothing thorough had been done until the past few months. The Etna Co. of Sacramento has put up hoisting works and sunk to a depth of 150 ft. The ore taken from this mine is different from anything known in this State and perhaps in the world, although it is said that there ie similar ore at Leadville, Colorado. It is a kind of gray sandstone, looking like fine concrete, and is thickly studded with sulpburets of iron, from the size of a pin point to that of a walnut. The ore taken out assays from $100 to $1,000 per ton. The parties working it have the utmost confidence in the mine and will erect a mill and reduction works as eoon as possible. The lead has been traced for 3 miles north, but there are no indications of it soutb of the Etna. A. Hayward is reopening the old Simmington mine, situated 500 ft east of the Empire. This mine was first located something over 20 years ago by John Simmington, who worked it periodically for 6 or 7 years, until he got mixed up with the killing of a Spaniard on Bishop flat (now Vanderpool's ranch), and left between 2 days, since when he has never been heard of. The mine has been worked occaeionally eince, a shaft 60 or 70 feet deep having been sunk. It is now owned by A. Hayward and J. Woolford. The latter has bonded his interest to the former, who has erected a whim and intends thoroughly prospecting the mine. Some people think that this is the mother lode and that the Empire is a kind of a hump hanging on the eide of it. Well, euch humps are convenient to have on hnud.

FROM SUTTER CREEK.—Cor. Amador *Ledger*, Oct. 22: The last set of tiubers was placed in the shaft of the Amador Consolidated on Monday night. Prospecting for the ledge will be inaugurated as soon as possible. It is intended first to prepare a place to store the debris loosened during the night shifts, so as to hoist only during tho day time, as it is tbought that all the rock extracted during the 24 hours can be easily raised to the surface during the hours of daylight. Drifts will be run, we understand, in 3 different directi ns. While sinking has been in progress 12 men have been employed, working in 3 shifts, of 8 hours each. When drifting has fairly commenced, it is thought this force will be materially increased. The Median mine at Amador City is keeping the Talisman mill running steadily. The copper plates are said to indicate that the rock is turning out handsomely.

VOLCANO.—Amador *Ledger*, Oct. 22: That Modoc rock that was crushed at Mace's mill has been all the talk for some time. The first crushing was a run on 100 tons, and everyone expected something big in the clean-up, for rock that will assay over $10 per ton surely ought to mill over $30. But just imagine the surprise when it was found that the average per ton was $9.50. The last crushing was 373 tons, and during the run 2 special watchmen were placed in the mill, the result being that 90 ozs of gold were cleaned up and brought to town last night. It seeme quite a difference when it is remembered that all this was the same quality of rock. The V. G. G. M. Co. are making every preparation for a big run during the winter. They are having an immense reservoir built to hold water when the rains have ceased. Sinking tho shaft at the Golden Gate continues with flattering prospects. The Downs mine may s.art up some time in the near future. Several new ledges are being prospected around in the hills.

MISCELLANEOUS.—A vein of rich ribbon rock was struck in the Morgan tunnel last Tuesday. Samples shown in Jackson look encouraging. We are glad to be able to state that good ore is being taken from the Kelly mine, in Hunt's gulch, lately purchased by Boston capitalists. Two experts are at the Amador Oravel Co.'s claim, overhauling the books showing the transactions for the last 2 years.

CALAVERAS.

BIG NUGGET.—Calavcras *Chronicle*, Oct. 20; Mr. Chas. Schlund, banker in this place, has on exhibition at his place of business a nugget of solid gold, obtained from one of the claims in this vicinity, weighing $200. Such *chispas* are a little rare now-a-days, but they have not all been taken out yet, it seems. It is a very nice thing to look at, and much nicer to have. We wouldn't mind having a few such pieces

GRAND ENTERPRISE.—*Mountain Echo*, Oct. 18: The Union Water Co. have just completed their re ervoir, located about 40 miles east of Murphys. It is a massive structure built somewhat in the form of a pyramid with wings extending from the base. One of the wings is 900 ft in length, 18 ft thick at the base, and 7 ft at the top. The main dam over the river is 175 ft in length, 34 ft thick, and 9 ft on the top This grand structure will cover an area of 8,000 acres, and will average from 8 to 20 ft in depth. The cost of this work is estimated at $10,000. There will in future be no lack of water for mining pusposes, and it is to be hoped that the hardy miners will do their utmost to develop the minee.

DEL NORTE.

COAL AT POINT ST. GEORGE.—Del Norte *Record*, Oct. 10: The work of prospecting for coal at Point St. George is being steadily pursued, and the progress so far made is as good as might be supposed, since the work is done entirely by hand. Although the party, with Mr. P. Emmetsburg at the head, during the 2½ months they have been engaged, have encountered numerous difficulties, in the way of bad ground, insufficiency of implements, etc., they have penetrated to the depth of 183 feet, and for half that depth bad, up to Sunday last, put down the pipe (the diameter of which, being the same as that of the hole, is five inches), which, in any manner of ground, becomes necessary to do good boring, or to carry on the work with any degree of safety against accidents that might occur in caving or filling in. During the fore part of the present week the men were busily engaged in pumping and priming out the cut, preparatory to extending the pipe about 80 ft farther down, after which their intentions were to again resume boring. At a depth of 170 ft their labors were rewarded by the bringing up of "outcroppings," of a reasonably good quality, from what was supposed to be a vein about a foot thick. The vein, or layer or aand coal, was then lost, but its discovery gives foundation for their hopes and affords excellent prospects, of their early striking a main, or a larger lead. Together with this fact may be mentioned that of there being plainly visible at low tide in the winter season, when it is not covered with sand, a large cropping out of the ledge a short distance out in the ocean opposite the place where work ie at present being done. The latter shows conclusively that coal abounds in that vicinity, while the former furnishes good indications that to strike it as good a site has been selected as could anywhere have been.

EL DORADO.

SICKENS.—*Mountain Democrat*, Oct, 22: D. W. Fox, near Johntown, has 10 acres of ground that have been mined down to the bedrock half a dozen times, then filled up with clickens, from which he cuts 2½ tons of timothy and clover per annum.

MINING AT VOLCANOVILLE.—R. O. Hart, a Grass Valley miner of extensive experience, representing a company of abundant means, went up to Volcanoville 2 weeks ago last Monday, took charge of the Josephine (formerly known as the "Dore") mine, started up the 10-stamp mill, and the indications are highly promising.

THE TEXAS HILL GRAVEL MINE.—At this mine, simultaneous with the erection of the 10-stamp cement mill, there are other active preparations for operations on a large scale. Mayer & Patten, at their blacksmith shop on Main street above Bedford Avenue, are building 12 cars for this mine, 10 of which are of ordinary size and 2 are to be extra large. A reliable and experienced miner, who recently visited the Texas Hill mine, tells us that he was unable to gather up a double handful of gravel anywhere in it that did not yield a fine prospect.

MINING AT HOOSIER BAR.—At Hoosier Bar J. W. Brown, of Greenwood, this county, and associates, have adopted a new invention for elevating gravel by hydraulic process to such a hight as will give sufficient fall to their sluices, and dumpage for their tailings. The elevator is an iron pipe 10 inches diameter, set at an acute angle, the top of which discharges into the head of the sluice boxes. One stream of water forces the gravel into the lower extremity of the pipe, whence it is driven upward with great force by another stream from a "Little Giant." By this means, for every 100 ft of pressure in the driving current a column of gravel and water can be driven upward 20 ft. The Hoosier Bar elevator is giving eminent satisfaction and has opened up some very rich ground. Last Friday afternoon, from one pan of bedrock gravel, Mr. Brown washed out over $25, and in cleaning up the bedrock after 1 day's run he and four hands panned out 10 ounces of gold.

KELSEY DISTRICT.—Georgetown *Gazette*, Oct. 21: The clean-up just made at the Gopher mill of one month's run from the Bowlder ledge, is highly satisfactory to the owners. The mill works to a charm, and the water power cannot be surpassed by any in the county. The mill is now running on ore from the Gopher ledge, crushing 20 tons per day, with very good results. About the mine everything looks well. They have run a tunnel 480 ft, tapping the incline shaft of 158 ft in depth, which gives great facilities for working the mine. In a crosscut in the tunnel the ledge is 15 ft from wall to wall, and in the incline it shows all the way from 4 to 10 ft ledge of fine milling ore. Mr. Aldersly, the Superintendent, is getting the mine opened miner-like, and soon will have things in shape so that 10 more stamps will have to be added. All outside works are getting in a number one shape so there will be no delays when winter sets in. Mr. Frank, one of the owners, is up on a visit, and his company is satisfied of having a good mine. The Judge mine, or old Dagget ledge, is being prospected again. The Superintendent, Mr. Ramail, has gone to San Francisco to make arrangements for erecting a 10-stamp mill on this mine. The Lone Jack mine owned by Mr. Jensen, will make a good showing this coming winter. Mr. J. is driving a powder drift to shake the country up about him. Kelsey township is showing up a number of good mines.

INYO.

WAUCOBA.—*Inyo Independent*, Oct. 22: J. Wal. Phillips and A. McKellips, representing a recently organized New York Co., are over in old Waucoba district, intent on developing some very promising mines in that region. They will put in some two months' work or more, and we hope for some good reports.

NEW DISCOVERY.—Samples of ore were brought in on Monday last from a newly discovered ledge in the Inyos, a little north of the Beveridge district. Two assays made by Mr. Woodhull showed respectively: gold, $80.33, silver, $31.42, total, $111.75; and gold, $12.50, silver, $81.08, total, $94.18.

GOLD MOUNTAIN.—A late letter from the Gold Mountain brings information that Supt. Ferris is pushing work on the new line water pipes to the extent of putting on every man that can be worked. Work in the mine has been suspended until the completion of the new hoisting works, which will require but a short time, when the shaft will be sunk 300 ft deeper as rapidly as possible. George D. Roberts, the original promoter of the State Lines, is now in San Francisco, enroute to the mine.

THE HIRSCH MINE.—A gentlemen who has visited this mine during the past week informs us that the late work done on the property shows a strong and well defined vein of ore 3 ft in width. This is practically a gold mine, although a wonderful variety of rich ores were found near the surface. At first, several tons of beautiful red oxide of copper was taken out, with grains and small masses of native copper running through the ore, carrying considerable gold. Then came a vein of rich silver lead ore about 6 inches thick on the hanging wall. Assays of this ore show 100 ounces of silver, and $20 in gold per ton. Finally the copper gave out and gold-bearing, copper-stained quartz now fills the vein. The gold can be seen in a large portion of the ore, and assays run from $30 to $150 per ton. This is one of the most accessibly located mines in Owens River valley. It is situated about 1,000 ft above the valley proper, and about 2½ miles from Owens river. The distance from Independence is about 9 miles, with a good road to the mine. The Hirsch is no doubt a valuable property, and in view of the rich developments in Beveridge, which is but a short distance from the Hirsch, this mine should not long remain idle.

MONO.

NIGGET.—Bodie *Free Press*, Oct. 21: Supervisor William Whetherill came into Bodie Thursday from his Dogtown placer diggings, having with him a nugget which he took out last week of about $50 value. It is the largest nugget which was ever taken out this side of the Sierra. Mr. Whetherill has several hundred acres of placer ground, and an ample supply of water, and is confident of realizing from it another fortune, equal to that which he realized from the Indian Queen.

THE BODIE TUNNEL MILL.—This mill is fast approaching completion. The roof is being shingled and the foundation for the engine is nearly finished. By the end of the present week the engine will no doubt be set up. The framework for the rock breakers, pulverizers and pans is also completed. It is expected that the machinery will be in operation by the middle of next month. Material for running the mill during the winter will be all on hand before cold weather sets in. It is anticipated that the Bodie Tunnel mill will have a very successful run. When finished it will be a very complete affair.

BODIE.—*Free Press*, Oct. 22: A large number of the Bodie mines have made preparations for working during the coming winter. A great deal of wood and other supplies have been, or are being laid in, and the outlook is more encouraging than it was two or three months ago. It is encouraging in this way: so long as a mining company has men at work underground, the prospects are good that an ore body may be found. The history of mining during the past 15 years is full of lessons. A mine may not be worth $500 to-day, and a single blast may send the stock up 1,000%. Just so long as a mine in Bodie district has men employed beneath the surface the prospects are encouraging. A great deal of attention is being attracted to the Lent shaft. The ore vein on the 705 level is rich and full of promise. A number of the other properties are looking well, and especially is this the case with the Bodie tunnel, Oro and Addenda. There is no change in the Syndicate, the mill being constantly employed on ore from that mine. The Champion is also prospecting well, while the Tioga has been doing some good work on the lower levels. Those who are interested in Bodie stock have no reason to feel discouraged at the prospects, for, as stated in the outset, surprising developments are often made in a day, and at a point often where least expected.

NEVADA.

MT. AUBURN SUIT DOWN.—Nevada *Transcript*, Oct. 20: Orders have been received from San Francisco to close down the Mt. Auburn quartz mine. No reason is given, and we understand the mine is looking finely at the present time. There were only 8 men employed on the works, and they will find work without delay as there is a very great demand for laborers.

IMPROVEMENTS AT THE IDAHO.—Grass Valley *Union*, Oct. 20: The Idaho Mining Co. are at present engaged in making more extensive and valuable improvements in their pumping machinery. A new 20-inch engine and a large pump for the purpose of handling the water in the mine are being put in place. Work on the stone foundation is being prosecuted with vigor, and when the pump is set to work there will be no danger of the water ever getting the better of the miners. This new pump will be for the purpose of raising the water from the bottom of the mine to the 800 level of the old shaft, from which it will be raised by the present big pump. When everything is completed it will do away with a great many extra pump rods and bobs now in use, and the water can be handled with much more ease. The foundation for the engine will be of solid masonry of the most substantial kind. From present appearances, and the improvements the company are constantly making, it would seem that the Idaho would continue to be worked at great profit for years to come.

NEW YORK HILL MINE.—*Tidings*, Oct. 22: There are many rumors about affairs of the New York Hill mine, and street talk has it that a considerable lot of crookedness has been discovered there. We believe, or rather we suppose, that the mine authorities are investigating the matter. When anything like proven facts appear we will give them.

THE AMERICAN MINE SOLD.—North San Juan *Times*, Oct 22: On Saturday last the American mine was sold under the hammer by the Sheriff. The Yuba Tunnel Co., a corporation, were the purchasers. It was sold in 4 different lots. The mine ground brought $80,000; the joint stock ground was bid in at $10,000; the Union ground at $1,500, and the old American ground proper was bid in at $21,000, making a total of $72,500.

SHASTA.

IRON MOUNTAIN.—Shasta *Courier*, Oct. 22: Yesterday morning I saddled my steed and set fourth with the avowed purpose of paying a visit to the Lost Confidence mine, to view for myself those marvelous deposits of silver-bearing ore, of which I have heard such report. found the Superintendent, Mr. Sallie, who is an owner in the mine, engaged in packing, preparatory to shipment, a large quantity of fine looking ore. The lower tunnel is in 320 ft, and is about 100 ft below the surface, and 90 ft above this another tunnel has been run a distance of 120 ft, most of the way through good paying ore. From the termination of this tunnel a shaft is being sunk on the ledge to strike the lower tunnel. I understand the owners of this mine contemplate the erection of a 30-stamp mill at no distant day, there being ore enough in sight to justify them in the undertaking. Messrs. Camden & Magee, the principal owners of this valuable property, deserve great credit for the energy and enterprise they have displayed in prospecting and developing this mine, while there are other mines in this locality that will be more or less benefited by the developments made in the Lost Confidence. The owners of the neighboring mines have manifested a disposition to lay low and let the owners of the Lost Confidence do the prospecting which adds value to all the mines in the vicinity. Notwithstanding this, the owners of this rich mine have persevered until after a year of patient toil and the expenditure of thousands of dollars they now have every reason to believe that they will receive abundant returns for their labor.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—*Enterprise*, Oct. 23: We are still engaged in opening up and cleaning out the drifts and winzes connecting with the Old Con. & Virginia shaft. During the past week 81 tons of ore have been extracted and sent to the mills; assay value, $24.

SIERRA NEVADA.—On the 2700 level the joint Union Con. winze has been sunk and timbered 8 ft. The joint Union Con. east drift has been extended 24 ft, and the west drift from the joint winze, 20 ft.

UNION SHAFT.—Are cutting out a bob pit at the 2000 station, and are retimbering the 1600 drift to the Sutro tunnel.

CON. VIRGINIA.—We are still engaged in opening out the drifts connecting with the old Con Virginia shaft, cleaning out winzes, etc.

OPHIR.—On the 1600 level are cutting out a drain and cleaning out sump in winze. Drill hole No. 1 has been extended 200 ft.

UNION CON.—On the 2700 level the joint Sierra Nevada east winze has been sunk and timbered 8 ft, and the joint Sierra Nevada east drift has been extended 24 ft and the west drift about 20 ft.

YELLOW JACKET.—On the 3000 level the north lateral drift was run 36 ft from the connection with the north winze, and the east cross-drift run 32 ft from the same point. The ground in both drifts is quite hard and free of water. At the switch east of the shaft, same level, we have extended the south lateral drift 33 ft from the same, and an east cross-drift 25 ft. The ground in both is hard and dry.

SUTRO TUNNEL.—The Prospect Drift at Point 4,035, South Lateral, has been extended 7 ft, making the distance from the south lateral 113 ft. At a point 108 ft from the lateral tunnel a crosscut was run east in the vein and has now reached a point 20 ft, measuring from the center of the drift. The crosscut passed through first, a clay seam, then a vein of quartz about 18 inches in width, then followed soft porphyry and quartz mixed; next was encountered a strata of very fair looking quartz, and finally vein porphyry, which we are now running through. As the porphyry is much softer and the quartz gives better assays than was obtained from the other crosscut, and the vein wider, the indications are more favorable northward. The flow of the water from the mouth of the tunnel is equal to 4,977,682 gallons per 24 hours.

CANDELARIA DISTRICT.

NORTHERN BELLE.—*True Fissure*, Oct. 22: During the week the shaft levels have presented few changes to note. The intermediate, between the first and second levels, has shown some improvement and is turning out considerable ore daily. There is also a slight change for the better in the intermediate, between the second and third levels. The eleventh and twelfth levels are yielding about the same quantity and quality of ore as at time of last report. There is a large amount of work being done in the levels above, and the appearance of that part of the mine is very much the same as last week. The daily yield of ore has been about 80 tons. Mill No. 2 started up on Thursday, the repairs not taking quite as long as was expected. Mill No. 1 has been running on half time for a few days. Bullion shipments for the week ending Oct. 19th, $17,005.53. Shipments on October account to Oct. 19th, $47,038.58.

MOUNT DIABLO.—The north crosscut from the east drift from the bottom of winze No. 1, third level, shows a small streak of ore averaging $50. The north crosscut, 40 ft above this winze, shows a fine ledge of ore 4 ft wide, assaying $80. An advance of 7 ft has been made on this ore and the prospect is promising. The north crosscut from the bottom of winze No. 4 shows no change; total length 46 ft. The east drift, 3d level, shows considerable improvement, and has a bunch of good ore in the hanging wall, of which the extent is not known as yet. Fourteen ft advance has been made in the drift. There is but little change on the 2d level. A winze has been started from the east drift to connect ore body followed in the 3d level. The winze in the gulch is down 134 ft.

ESMERALDA DISTRICT.

THE CORTEZ.—Esmeralda *Herald*, Oct. 20: The building of a carpenter shop and coal house has been commenced, and preparations generally are going on about the mine to enable the company to prosecute work during the winter. Sinking in the incline is being pushed in order to reach the level at which the lower tunnel will tap the ledge at the same time that the tunnel strikes that point. The mine is looking splendid at every point where work is going on.

POWELL'S MINE.—A. Powell, owner of a mine near Parker's soda marsh, about 9 miles east of Aurora, called to see us last Thursday. He said 3 tons of ore taken out had been sent to Dayton for reduction, but as yet he had had no returns. Assays go high up in the hundreds. The incline shaft is now down about 75 ft, and has been in ledge matter from the top to the bottom. Mr. Powell thinks he has a rich mine.

EUREKA DISTRICT.

STRIKE IN THE PROSPECT MOUNTAIN TUNNEL.—Eureka *Sentinel*, Oct. 23: News was brought in yesterday that an important strike had just been made in the Prospect Mountain tunnel. Some of the ore taken out was on exhibition at the Jackson House. The tunnel is on the west side of Prospect mountain, and is some 1,800 ft in length. The ore was struck in the face of the tunnel, and is said to be 500 ft deeper than the ore recently discovered in the Eureka tunnel. We were unable to learn the character of the ore. This is exceedingly good news for Eureka.

ANOTHER BONANZA IN THE RICHMOND.—Eureka *Sentinel*, Oct. 20: On Tuesday last the miners working in the west drift on the 6th level of the Richmond mine encountered a new and extensive body of ore. It is not yet known how large the body is, but it is thought to be extensive and very rich. Previous to the find there was ore enough in sight to keep the furnaces running for a year. The probabilities now are that there is an abundance of ore for a two years' run. After 11 years' extraction it would seem as though the Ruby Hill ore body was inexhaustible.

FLORENCE DISTRICT.

LOUISA.—Cor. Belmont *Courier*, Oct. 20: News from Florence district is encouraging. The Louisa Co. is pushing work on their claim, the Louisa mine, which opens out fine.

GRANTSVILLE DISTRICT.

THE ALEXANDER.—The chloride stope between levels No. 4 and 5 is looking well and from which we are now extracting about 45 tons of ore per day.

THE BROOKLYN.—In the Brooklyn, No. 3 level, drift was advanced 20 ft during the past week, making total length to date 208 ft, in face of which there is plenty of quartz showing little spots of sulphurets. The ore body on level No. 2 continues to look well and produces the usual amount of good ore.

ALEXANDER MILL.—The mill is running steadily and doing splendid work.

PROSPECT MOUNTAIN DISTRICT.

STRUCK IT RICH.—Eureka *Sentinel*, Oct. 22: John Heubner, who has been prospecting for several days in Prospect Mountain district, has returned, and reports that he has found croppings that assay $130 per ton. He says there is a great abundance of the stuff, and that it is free milling ore.

RELIEF DISTRICT.

ANTIMONY MINE.—*Silver State*, Oct. 18: Emmons & Young, of Lovelock, are making arrangements to work their antimony mine in Relief district. San Francisco men examined the mine, and were so well pleased with its appearance that they furnished $1,500 to prospect it, and if satisfied with it when that amount is expended, will purchase at a stipulated price. The ledge is very large on the surface, and the ore carries a high percentage of metal.

TYBO DISTRICT.

TAILINGS.—Cor. Belmont *Courier*, 20: Lieutenant-Governor Adams is testing a load of Oila mill tailings at the Tybo Con. mining company's mill. If satisfactory results are obtained he will build a Whits roaster at the Reveille mill, as he has several thousand tons of tailings there. Business in Tybo is very dull.

ARIZONA.

BISBEE NOTES.—Tombstone *Epitaph*, Oct. 21: From Messrs. C. Ollroy and William Wallace, who came in from the great copper camp, yesterday, we learn that mining matters are lively there. The Neptune Co. have made a strike on the Neptune, between numbers 1 and 2, that is looked upon as of decided importance. They are busy hauling their ore to the smelter at Hereford, accumulating a large quantity preparatory to the starting up of the furnace. The rock-breaker was met on its way to the works, somewhere between Charleston and Hereford. After this is set up the furnace will start up. The Copper Queen Co. are erecting a third smelter, which will give them a capacity of 600 tons of copper per month. It is well known that their output is only limited by the plant for reducing the ore. However, with the addition of the new furnace, their profits will be something nice. Take copper at its present price, 18 cents per pound; their copper brings $300 per ton, and their output $216,000 monthly, of which one-half is net profit. This will enable them to pay 4 % on the par value of their capital stock, with a surplus for the reserve fund of $8,000 per month. The developments on prospects throughout the district are of a very satisfactory nature. On the Golden Gate they are down 14 ft, with an ore vein 12 inches wide, and several smaller ones, all improving with every foot in depth. Black Jack is also improving, and gives promise of making a large mine. Work is about to be started up on the Broad Gauge and Silver Spray, both splendid prospects. The superintendent is expected every day to start up work on the Atlanta, which recently sold for $40,000.

BRITISH COLUMBIA.

CARABOU DISTRICT.—The miners in this district have done moderately well the past summer, and although a good many of them are now leaving for the lower country, many of the deep claims will continue to be worked throughout the winter. There has been quite a good deal of mining going on in a small way of late along the Frazier, but here, too, the season will soon close. In the Kootemai country several companies are at work, the principal party engaged there being the Black Hills Co., who are vigorously pushing operations on Cherry creek, notwithstanding the death of their late Supt. in charge, Joel S. Mead, the organizer of the enterprise. This is a strong company and it is confidently believed that they will achieve such a success the coming spring, if not before, as will give a great impetus to mining in that quarter.

COLORADO.

CASCADE DISTRICT.—Georgetown *Courier*, Oct. 20: The wagon road from Spring gulch to the mines on Ute creek, which the miners of that section have been at work on for some time, has been completed, and already shipments of ore have commenced. Last week the Silver Rag mine, owned by T. E. Schwartz and C. E. Bigelow, of Georgetown, and Martin Brimmer, of Boston, shipped to the Idaho Springs Sampling Works 2,400 lbs. of first-class ore that milled 161 ounces of silver to the ton, and 2,000 lbs. of second-class that milled 50 ounces. The lode is the eastern extension of the Muscovite, and is opened by two adits, the lower one 250 ft long, and the upper one, which is now being driven, 50 ft long. The lower adit shows from 0 inches to 2 ft of ore like that milled, and the upper one has not yet passed through the broken ground to the ore vein. The owners intend to work the mine steadily through the winter. A shipment has also been made, of several tons, since the road was completed, from the Great Eastern lode, which is the western extension of the Muscovite and owned by Dan Doyle, of Georgetown. On the Muscovite one contract only is being worked, as they are waiting the return of Mr. Worthington, who is now in England, and who is expected back next month, after which it is thought that the mine will be worked extensively.

RED ELEPHANT.—The Red Elephant Co. has recently given a lease for two years to Thomas Welch, Sheehan, Wood and others, on that part of the mine below the Clery adit on the White and the Sub level of the Bowlder Nest, which lies west of a point about 200 ft east of Swartz shaft on the White. The lessees are to timber the Swartz shaft in first-class shape and continue down to the Clery adit and then sink into the leased ground below the adit; also, to put up a suitable hoisting plant and a commodious shaft house at the surface. The lessees have commenced grading for the shaft house, which will be 40x50 ft in size with a wing for boiler.

IDAHO.

BELLEVUE SMELTER.—Wood River *Times*, Oct. 10: The Avon smelter, which has been Bellevue's boast and pride for months past, is about to be shut down, probably never to be "blown in" again. It is an old-fashioned affair, made of fire-brick and rock quarried on the ground, and the work was of the most primitive character. Altogether, the furnace was not in operation over three weeks and did not probably smelt a single charge successfully. It was impossible that it should. The primative nature of the establishment forbade that. Joe Douglas, the Comstock millionaire, who has supplied the funds with which to run the institution, arrived in Bellevue this other day. As soon as he saw the works he made up his mind that they would not, could not pay, and concluded to shut them down permanently. The plain truth of the matter is, that Mr. Martin, in his anxiety to so save his patron's cash, did not spend half as much money on his works as he should have done. About $5,000 expended for a Pacific water-jacket galena-silver smelter would have given him first class works and a furnace with which the samplers and smelters of this generation are familiar, and the result would have been satisfactory.

SMELTING ORE IN THE SAWTOOTH RANGE.—C. W. Cortright, manager of the Columbia and Beaver companies, passed through town on his way to Ogden. Mr. Cortright stopped long enough to state that a large deposit of smelting ore had been discovered in the Sawtooth range, and that it had already passed into the control of a strong company who would erect a smelter in the spring.

W. H. PETTIT, Supt. of the Monarch mine, of Atlanta, who came through to Hailey last Wednesday, says that the toll-road from the Sawtooth divide to Ketchum, a distance of about 35 miles, was lined with teams hauling machinery and supplies for the Columbia and Beaver companies, at Sawtooth.

HOISTING WORKS FOR THE ORNAMENT.—Machinery of a capacity sufficient to sink 500 ft has been purchased for the Ornament mine, up Croy's gulch, and the contracts for erecting the works are let. They must be completed by the 1st of December. This will be the second hoisting works in this section.

THE ROOKS GROUP.—W. A. Rooke, of Ketchum, is about to ship 30 tons of ore from the Rooks group of mines, on Warm Spring creek. Of this amount, 10 tons will be sent to Kelton, 10 tons to this city, and 10 tons to Salt Lake. The results obtained will determine to which place the ores of the mines superintended by Mr. Rooks will be shipped in future. Mr. Rooks is operating for a strong Boston company, who have paid in an ample working capital. They are in no hurry to get returns, and they propose to see where they can do the best. Four of the company's mines are now ready to ship an aggregate of 50 to 60 tons per day. These are the Ontario, Warm Spring, Sunday and Gopher. The Warm Spring mine has a 6-ft vein, half of which is galena. These mines will be worked all winter. Next spring they will yield large quantities of ore.

ENGLISH COMPANY.—*Idaho World*, Oct. 18: An English Co. bought a number of ledges on North Fork of Salmon last summer, paying $83,000. A 10-stamp mill was erected, but was found to be inadequate to crush the ore as fast as taken out, so the company recently put up a 20-stamp mill. The rock averages only $5 per ton, gold, yet the company claims that it can be profitably worked. Boise county has scores of ledges, the ores of which will mill not less than $5 per ton in the poorest spots, and they measure all the way from 2 to 10 ft in width. The ores are gold-bearing, free-milling, and easily taken out. Only a few of the mines are being worked, for the reason that the owners are without the means to put up mills, and when the rock is to be hauled many miles for reduction, only the ores of the richer seams will leave a margin for the owners after the expense of hauling and milling. With mills in close proximity to the mines, the poorest of the rock would more than pay the expenses of extracting and crushing.

MONTANA.

BUTTE BONANZAS.—*Inter-Mountain*, Oct. 20: On the middle vein in the 300 level of the Magna Charta 12 men are stoping on a body of ore between 2½ and 3 ft wide, and assaying over $200 per ton. The quartz shows a profusion of native silver. The strike of silver ore recently recorded in the Colusa was made in the face of the 160-foot cast drift, at a distance of about 400 ft from the shaft. The silver assay value of the ore is said to be about $70. The mine is now producing about 100 tons of ore per diem. There are no new developments to report in the Bell though the extension of this west 300-foot drift is being prosecuted with customary vigor. The ore in the face retains its usual characteristics, being as rich as ever in silver and copper. The ore now being hoisted is the richest ever taken from the mine. On the Morning Star, which, considering the amount of money expended in its development, has been, and perhaps will continue to be, one of the most profitable mines in the Butte district, operations are confined to the extension of the north crosscut from the bottom of the 200-foot shaft, from which the face is now about 12 ft distant.

STEVENS.—*Inter-Mountain*, Oct. 22: The developments of the past week have very materially improved the appearance of this property. The face of the east 200-foot drift has been forwarded 85 ft from the shaft, and within the past 20 ft as the ore shoot was approached, the character and richness of the ledge have undergone a marked and important change. The pay ore was previously mixed with clay and quartz matter, but now shows clean and solid, varying in width from 15 to 30 inches, and averaging about 2 ft across. According to samples carefully taken this morning, the ore in the face assays 80 ounces in silver and $20 in gold.

LEXINGTON.—At the bottom of the main shaft, and in the face of the 200-foot north crosscut, within the past few days, heavy bodies of water have been encountered, which so rapidly increased in volume that operations were temporarily suspended. A ledge has evidently been struck in both places, but as the rush of water allowed no time to investigate its extent or richness, it cannot be stated whether or not it was the main ledge.

ALICE.—The Alice mine is closed down for a few days to admit of repairs to one of the boilers. The mills will continue running, an abundance of ore being already extracted to keep the stamps in operation. The mine is reported in excellent shape.

ANDY JOHNSON.—Mr. Barnard was found in excellent spirits this morning over a strike made within the past few days in his very promising though yet undeveloped property. A crosscut north from the bottom of the shaft and a drift run west on the old ledge have developed a large body of very rich ore.

MAGNA CHARTA.—Mr. J. R. Walker, President of the company, this morning informed our reporter that sinking was to-day resumed from the 300-foot station, it being the intention to add another 100 ft to the depth of the shaft as soon as the work can be accomplished, and at the earliest practical date to continue the work until the Magna Charta shall have been explored to a depth equal to that of the Alice.

NOTES.—At the Clear Grit, upon which a fine shaft house has recently been erected, the incline shaft is being enlarged into 2 compartments, and sinking will soon be continued. Powerful hoisting machinery is already in position. At the Moulton a force of men is busily employed in making preparations for placing the new machinery in position.

UTAH.

COPPER.—Silver Reef *Miner*, Oct. 18: A gentleman just up from the Grand Ouich copper mines informs us that everything looks promising there for a large bullion output in the near future. The 2 stacks now running are turning out about 7 tons of base ingots per day—worth $200 per ton at the works. The only disadvantage encountered so far is the scarcity of water, which it is expected will soon be overcome, as pipes are being laid to bring water from a source about 9 miles distant. Five more stacks will be erected within the next 60 days, which will give a proportionate bullion yield. At present about 40 men are employed about the works. The indications are that Copper Mountain district will prove in all respects equal if not surpass Grand Gulch. Messrs Ellerbeck & Co. have been developing some claims there that show exceedingly well. The ore is far less rebellious than any yet found in that zone, and recent experiments have proved very gratifying to the owners. Arrangements are now being perfected to put up one or more smelters at once.

UPPER Calaveras county has a fine belt of comparatively untouched timber.

Gold.

Mr. Thomas Cornish, M. E., late of Australia, and the well-known author of "Gold Mining, its Results and its Requirements," has contributed the following excellent paper to the London *Mining Journal*. It reads:

Gold is the metal of all other products of the earth most eagerly sought after—beautiful in appearance, soft and ductile in its nature, it possesses charms and attractions to the ignorant savage, as also to the most highly cultured. No mind is either too high or too low to despise gold, either for its usefulness and beauty as ornaments, or for its intrinsic value as a purchasing power. It has in the past, and will in the future, be the precursor of much good and evil.

Our gold supply, that has such an immediate and direct effect on the finance, trade and commerce, is deserving of more attentive consideration than it has hitherto been accorded. It is not my intention in this work to enter into the history of the discovery and production of gold in past ages; but to treat, as briefly as possible, on the discoveries of the present age—its mode of production, and the means of increasing the supply.

The Golden Era.

The golden era of this age dates from the discoveries in California in 1848, and which were followed by the discoveries in Australia in 1851. Previous to these discoveries the estimated quantity of gold in circulation in the world was between £400,000,000 and £500,000,000; but during the past 30 years the gold miners of California, Australia, New Zealand, and other places, have produced from the earth and distributed throughout the civilized portions of the world about twice the quantity, or between £800,000,000 or £900,000,000. This vast wealth, or new purchasing power, has been put into circulation throughout the channels of trade and commerce by, comparatively speaking, very few men. I do not think there have been more than 250,000 men engaged in gold mining. The results of their operations have been absolutely wonderful, giving an immense impetus to trade, thereby improving the general prospects of mankind—developing new sources of industry, trade and commerce and increasing the world's wealth in proportion.

The production of gold being of such immediate and direct importance to finance, trade and commerce, it is desirable that the question of its supply should be carefully considered. The time is opportune for the discussion of the subject, and I will endeavor to give an outline of what I consider have been the results of gold mining on the world generally, the Australian colonies particularly, and the necessity of encouraging the industry, thereby increasing the supply of gold, as also some of the requirements necessary to place mining on a sounder basis, to produce more satisfactory results than are likely to be arrived at from the system under which it has mostly been carried on.

Gold mining may be termed a new or novel industry; that is, so far as relates to its being made a special feature of attraction and employment to a large number of enterprising men, who, since its discoveries (1849), have pushed forth into various parts of the world, and by their labor, aided only by the most primitive appliances, have created a wealth previously unknown, of such vast proportions that its production has been the means of revolutionizing the wealth, trade and commerce of the civilized portion of the globe.

Gold is real wealth, and the standard by which all other wealth is measured. Its production is the creating of a new purchasing power—not only so far as its intrinsic value is concerned, but it is a wealth that when produced is the germ or means of producing additional wealth. It is different in its results from that of other productions; as it is not consumed, worn out or destroyed, its influence and its motion may be termed perpetual.

The unexampled progress and the increased prosperity of the world during the past 30 years, must, I think, be chiefly attributed to the enormous supply of gold during that period. The sudden influx of this great new purchasing power, which has been twice the quantity of bullion the world previously possessed, gave to trade, commerce and finance such an impetus that could not have been derived from any other source or form of wealth.

The exact quantities of gold produced since 1848 would be difficult to arrive at, as much was taken away from the different countries without any record; but I shall not be overestimating the production, as follows:

California and other States of America	£600,000,000
Colony of Victoria	200,000,000
New South Wales, Queensland, New Zealand.	75,000,000
Other countries	25,000,000
Total	£900,000,000

In all probability the total amount of new gold distributed throughout the world by a few gold miners has not been much less than one thousand millions sterling. It is only by considering the effect of so enormous a quantity of bullion being added to the world's wealth in so short a space of time, that the mind can realize the special advantages that have been conferred upon civilized countries by the gold mining industry.

The Vital Importance of Gold.

Gold is the life blood of all finance, trade, commerce, manufactures, art, science, learning and every other kind of wealth for the comfort and essential necessaries of mankind. Its possession is the chief aim and consideration of all countries and civilized people. It is the standard stock of working capital of the world, from which all other sources of wealth are derived and radiate from. It is magical as well as real in its influence. The producer or possessor of any given quantity of gold can utilize it more readily, and to better advantage, than can the possessor of any kind of property of a relatively computed value of a similar amount.

To further illustrate my argument, the holder of a large quantity of goods of any description—say iron or corn—if the market be overstocked has to lower the price of the article, and the holder of gold can consequently buy more favorably and make his gold go further. Although there often is, and always will be, over-production of different classes of goods, there is no probability of there being an overproduction of gold. The more gold produced, the greater are the wants of those who produce it, thus causing an immediate and direct circulation of that wealth amongst the community in which it is produced or ultimately absorbed.

Gold and silver being the precious metals adopted as specie or as a medium of exchange and currency for regulating the value of other commodities for the use and benefit of mankind—they being, in fact, the axis on which revolves the finance, trade, commerce and general business, as well as the pleasures and necessities of every-day life—it is of the utmost importance to all that their production, as also the results and requirements of mining, should be made subjects for consideration and discussion more than hitherto has been done.

Before the gold mining era, the increase of gold for coinage was not in proportion to the requirements of finance, trade and commerce which have been so rapidly extending. Therefore, the gold discoveries seem to be a most fortunate, if not providential, circumstance to relieve the general depression then existing by opening up new countries for settlement, and avenues for capital and labor, for the benefit of a large portion of the civilized race.

It is, I am aware, a generally accepted belief by many that the production of gold is of no more value or importance to the State or the general good of the community than the production of any other article of commercial value such as food, drink, clothing, etc. I hold a different opinion, and believe that the production of any given quantity of gold is of more direct, immediate and permanent benefit than any other specific article of supposed equal value. The production of every ounce of gold is the means of putting four additional sovereigns into circulation, which are at once available for their possessors to utilize—although the cost of production of gold is oftentimes an absolute loss to the producer; that is, by fixing a given sum as the value of the labor spent in raising it. Yet the gold so raised is a gain and an advantage to the community, as it becomes an additional capital to the world's wealth, by affording additional means of extending its credit and securing its liabilities.

The Effects of Gold Mining.

The effects of gold mining or the production of new gold appear to be but little understood. It has become one of the most important industries of the world. It creates new wealth or purchasing power, and is the direct acting means of opening up new avenues of industry and trade, which, but for it would not be known or required. It has the same effect on the finance, trade and commerce of the world as steam has on locomotion. Trade and commerce being merely an exchange of commodities between the several sections of a community, as also between different countries, do not create new wealth, but merely concentrate existing wealth. I mean that finance, trade and commerce do not add to the stock of bullion capital; the wealth made by it is the enhancement of the value of properties and merchandise, and the extension of credit and paper currency on the business done. All the trade of London for a year will not add an ounce of new gold to the currency or actual capital of the world's wealth. Any party of miners producing any given quantity of new gold from the earth does more real good to the community than does the business transactions of any similar body of men engaged in any other occupations, because the gold so raised by the miners becomes an immediate addition to the working capital of the community by affording additional means of extending its credit and securing its liabilities. Thus any given quantity of gold raised is not only so much more money in immediate circulation, but it is also the basis from which radiates additional capital, in the shape of credit or paper currency, that is issued and recognized as money on the basis of gold. The continuous production of gold has become a necessity to the requirements of monetary institutions, by whose aid trade and commerce have extended to such a wonderful extent. Although the production of gold during the past 30 years has been of such vast proportions, its influence has been extended by means of credit and confidence in its security, by almost arithmetical proportion. No figures or calculations can estimate the real advantages that have been gained by its dissemination throughout the channels of trade and commerce.

Its results have been to raise the value of commodities, labor, material, land, houses and other properties. It has given an immense impetus to all trades, manufactures, arts, sciences, and learning. It has elevated the general tone of society and information of all classes. It has stimulated social pleasures and pastimes and engendered a spirit of enterprise in commerce, finance and industrial pursuits, never before known. The elastic credit based on the enormous supply of new gold produced by the miners has been stretched to a great extent, and the calculations and speculative operations of most all our large monetary institutions are based upon a continuance of the supply—so that if it were to happen that the gold miners ceased their operations, and suddenly stopped the supply, the trade and commerce of the world would receive such a shock that they would for a time be paralyzed. Monetary institutions would feel a like effect, and many of them would be ruined. It would lead almost to general bankruptcy, and an immense entailment of national and private expenditure. Any sudden or partial check in the production of gold, must, as a natural consequence, have a corresponding effect on the general trade and prosperity of the countries in which it is produced or in which it is mostly absorbed.

Adding to the List.

Last week we published an article from the *Mining Press* giving an account of large nuggets and masses of gold found in California in the past. From trustworthy sources we are favored with additional accounts of finds in El Dorado county, ranging above $500:

In the summer of 1857 the Aiken brothers, mining on Manhattan creek, two miles from Georgetown, found a nugget of gold, free from quartz, that coined $1,166. In 1857 Samuel Treeworgee, mining at Garden valley, found a slug worth $525.

Thomas Patten, of Placerville, informs us that in the year 1849 or early in '50 a nugget was found in what is now known as Illinois canyon, near Georgetown, worth $1,000. The locality was for a long time known as the "$1,000 canyon." Our informant believes the piece was sold to John T. Little, then a merchant at Coloma, now a real estate and money broker in San Francisco.

Geo. Beattie, of Georgia Slide, saw a nugget in September, 1850, of solid gold about the size and shape of a goose egg, worth about $1,000, found by a man named Jenking in Hudson gulch, at Georgia Slide.

In July, 1860, John B. Bennet and Milo Knox, now of Georgetown, found a piece of pure gold weighing two and one-half pounds, worth over $500, in the well-known Pennsylvania Seam mine at Spanish Dry Diggings, in a tunnel 45 ft below the surface.

About 1854 a mass of gold valued at about $1,100 was taken from a gulch near the Grit Seam mine by "Texas" and Jacobs.—*Georgetown Gazette.*

The Old and the New Prospector.

Eastern dabblers in mines are beginning to understand pretty well, of late, what the term "grub stake" means. The arrangement made by many Eastern companies with these so-called miners is by contract, binding them to work continuously for a certain number of months. In lieu of pay, the miners are to have food, tools and transportation, and from one-eighth to one-half interest in such mineral veins as they may find. The outfit of food, tools and animals for these contract prospectors is expensive. The free prospector fits himself out cheaply. For food he buys bacon, flour and yeast powder. His pack animal is a small donkey. He has a rifle and fish hooks and lines; and on these he, to a great measure, depends for his food. The men sent out by prospecting companies are promised canned goods and prepared food, which they never before heard of. They are equipped for a picnic and the work they will do is similar to that done by other picnic excursions. They will play cards under pine trees, smoke pipes by the banks of mountain brooks. They will prospect in an aimless way. If any of them shall accidentally discover a lead of any value, they will probably, if unwatched, quickly cover it and depart for other fields. If a lead of the desired poverty in gold and silver shall be found by any of these men, they will become enthusiastic over the great find, and slowly sink a shaft, or with great deliberation drive a tunnel. The mining camps of the Rocky mountains are filled with men who will prospect on a grub stake only. They wish to have the expense of their summer's excursion borne by a company, or by some credulous person known as a "grub staker." A prospector who works under a contract seldom finds anything until the contract he has signed has expired. This, with a few exceptions, has been the rule.

On the Yellowstone.—A corps of Government engineers is at work near Eagle Butte, improving and changing the channel of the Yellowstone. About 30 men and a complete outfit of barges and engines are on the ground and have been at work for a couple of weeks. At three or four places where the channel is bad between Glendive and Miles City, this work of improvement has been pushed rapidly forward and will continue until it freezes. This will make steamboat navigation an easy matter next summer.

Making Their Own Rolling Stock.—The machine shops, foundry and engine works of the Northern Pacific Company at New Tacoma, employ about 100 men. They manufacture all manner of engines, car wheels, and every description of cars, and supply all the roads in Eastern Oregon, Washington Territory and Idaho with cars and engines. They now have contracts for 450 passenger and freight cars.

The Hot Springs of the Great Basin.

As is generally well known, the great Utah basin abounds with hot springs, which differ greatly as regards the chemical composition and the medicinal properties of their waters, as well as their physical characteristics. Some of these springs occur in groups occupying great mounds formed by the mineral depositions of their own waters. Others are found isolated, presenting much the form of deep wells, the water coming just to the surface and flowing off in rivulets large or small. A few are spouting geysers, throwing up the water several feet above the surface of the ground. Great sanitary virtues are by the Indians claimed for the whole of them; these people, when ailing, proving their faith in the water by a free use of it, both internal and external.

Some of the most remarkable of these springs exist at points far away from the abodes and haunts of the whites, and aside from the much-traveled thoroughfares, and even the trails of the prospector, and have therefore been but little seen and rarely described, hardly any of this class having ever been utilized or even "taken up."

With the settlement of the country, the more accessible of these fountains of health have, however, been claimed and devoted to hygienic uses, a few, where sligibly situated, having become places of considerable resort. Such has been the case with the Failes hot springs, located about 15 miles northwest of Bridgeport, Mono county, and which, though discovered more than 20 years ago, appear to have been neglected until quite recently. Being on the trail leading across the Sierra from Sonora to the old Monoville diggings and Esmeralda, they were a noted camping ground in the early days.

Concerning the features and present condition of these springs, the Bodie *Free Press* has this to say:

These springs are located at the base of a range of hills, and cover nearly half an acre of ground. The proprietor, Mr. Sam Failes, has a hotel close by them and bathhouses over them. The springs are of different grades of temperature and mineral character, a portion being strongly impregnated with iron, and others with soda. Most of the springs are boiling hot, while others are simply warm. There is a hot mud bath into which rheumatics are buried, with the most remarkably beneficial results. A steam bath is arranged in one of the hottest of the springs. The bather sits in a chair, his head protruding through a hole, with the vapor enveloping his body. This bath will make a marble statue sweat like a roustabout, and must be very beneficial in many kinds of disease. The best fun, however, is the swimming bath, which is about 30 ft. square and four ft. deep. The warm water boils up all over it, which imparts to it a somewhat satanic aspect, but it is a most delightful place to bathe. A couple of empty casks afford the bather an opportunity to exhibit his agility, but it is doubtful if anyone has yet been found who can ride them with grace—or, indeed, without grace, for more than a second or two. About 300 or 400 yards from the springs is a hill about 100 ft. high, covered with rock of evidently aqueous origin. Upon climbing this hill it is found that the rocks mentioned simply form a rim to a deep basin 200 or 300 ft. in diameter, and about 50 ft. deep. It is evident that at this place there has at one time been a hot spring of immense diameter, possibly a geyser, throwing its water 200 or 300 ft. into the air. The bottom of the basin is now overgrown with weeds and sagebrush, and on its rim are growing small nut pine trees. These hot springs have been visited by a number of Bodie people during the past summer, and as the hotel is well kept, it is probable that the number of visitors the next year will be greatly increased.

Copper Product.

The *Engineering and Mining Journal* estimating the "output" of copper for the present year, derived from two parties who follow developments very closely, figures up one of these 63,300,000 lbs., and of the other 56,300,000 lbs. In the first, however, Arizona is embraced as producing 5,000,000, and in the last is entirely omitted. Touching the above estimate for Arizona, the Phœnix *Herald* remarks that it falls far short of the real quantity produced, as it is well known that the Copper Queen alone will reach 7,500,000, and the Clifton mine not less than 2,500,000, leaving out of the account other copper-producing mines which have not undergone sufficient development to warrant including them until shown to be more pronounced producers.

The Carrie copper mining company's smelter at Globe, started up on the 27th of September, and, except for a few hours' delay on account of their pumps, has been running successfully since. They turn out an average of 1,000 lbs. of copper every two hours, more or less, according to the grade of ore they are handling. The furnace is run with three shifts of men, and the company intend to keep it running right along, which they will have no difficulty in doing, as there are ample reserves of good ore in sight at their mines.

There are only about 60 people left in Hamilton, White Pine, a town that contained 3,000 people in 1869.

The Engineer.

Improving the San Joaquin.—C. E. Rhodes, a civil eagiaeer attached to the United States Engiaeer Corps in this State, has completed a survey of what is kaown as the Devils Elbow, on San Joaqain river, and reported to Colaael Meadell. The ohject of the survey was to fornish the latter named officer with data to enahle him to ohtain the necessary appropriation to cut a navigahle chanael through the bend aext year. Two hends in tho river have already been cut off, and steamers ply daily through the aew channels. The first is at the Loae Tree head, aad the second at the hend above Wakefield. These cuts are each 100 ft. wide, and are dredged to a deptb of 10 ft. at the lowest low water during the seasoa. Mr. Rhodes has had 109 saags removed from the San Joaqoin river, between Grayson sad San Josquin City, and has huilt several wing dams to rectify the chanael, and has therehy increased the depth of water in placcs from oae to five ft. On Monday aext he commeacee aa oxamiaation of the Mokelumae river from Woodbridgo westward to ascertaia what improvements aro needed, to insure the uaiaterrupted navigation of that stream.

The Panama Canal Scheme.—The reports ia regard to the proepects and progress of the Paaama canal scheme, arc quite unsatiefactory aad somewhat conflicting. There seems to be ahundant preparation, but very little actual work. At one time we are told that the cost of excavation will greatly excsed tho estimates, aud tben again we read that recent soundinge show immense depceite of clay, where hard rock was eapposed to exist, thue greatly reduciag the original eetimates. And now we are told that "tue Brussels excavators employed, work expensively, except in soft mud, and that the excavation at one of the new villagee is fouad to cost actually $1.25 per cuhio yard, instead of three cents, ae origiaally estimated." At a recent date, 70 of the total numbcr of workmen had already died, and there wae a great demaad for hospital accommodations. This latter convenience wae heiag largely extended, incluaiag graveyard convenieaces. Altogether, it would seem that the prospects of this magnificent engineering scheme are anythiug hnt brilliant.

Stopage of Power.—The invention of the French electriciaa, Faure, for the storage of eleotricity, eeems to have opened up a new field for iaventors. Our own electriciaa, Brush, has alreedy presented to the world a device for storing electricity, which, it ie claimed, is much superior to that of Fanre. Varioue devices for the prodnction and etorage of electricity hy wind power, hy oceaa wave power, and hy tidal power, have been euggested, and are now eageging the attention of iaventors. But the latest aaaonacement ia thie direction ie the following, which we clip from an Eastern exchaage: Modern science hae achieved a great victory ia at lengtb devisiag a meane of utiliziag the labors of prisoaere on the treadmill. The mill caa he connected with a dynemo-electric machine, aad eet to "etoriag energy" with Faure's accamnlator. The boxes of energy can he sold for honsshold purpeses. Behold, the solution of the prison lahor question.

Underoround Telegraphs.—Germany has demonetrated that it is practicable to put telegraph wiree under grouad. She hae no less thaa 221 towns and cities thue conaected, and four years experieace has proved satiefactory. Our own experimente are also satisfactory, hut it is certain that the old eystem will not he ahandoaed voluntarily. The Germans have adopted eimple aad inexpensive methods, coal tar heiag used for insulating purposes, with no provision for repair exceptiag instruments to locate fault. American devicee already approved hy experts, contemplato a eyetem far more complete, and no time should be lost in applying them in the most practical manner.

The firet electric railway in Upper Silesia has been erected in connection with the colliery of the Doanersmarckhutte Co., to snpersede the ordiaary horse railway. The current is conveyed by wire ropes, eupported on poles in the seme maaaer ae telegraph wires. The maximum speed will he eight miles per hour. The locomotive is similar to that exhibited two years ago at the Indaetrial exhibition, hut is eomewhat smaller. The line aad ite accessoriee were coastructed hy Messre. Siemens and Haleke.

Ocean Wave Power.—The Swales Ocean Wave Power Compaay hae incorporated, to furnieh power hy means of the action of ocean wavee and tidee with which to eupply ealt water for watering etreete, fluehing eewere, eupplying puhlic and private hathe, extinguiehing firee, and other public and private purpoeee; for driving machinery, compreseing air, generatiag electricity, and for all manufacturiag and commercial purpoeee. Capital etock, $5,000,000.

The Proposed Tunnel Under the St. Lawrence.—Notice was recently made of a echeme for tunneling the St. Lawrence river at Montreal. It ie now reported that the echeme ie likely to he abandoned in favor of a hridge, the English memher of the Tunnel company having joined a railway company holding a charter for a bridge across the St. Lawrence near Lachine.

Useful Information.

Seasoning Timber.—With the increaeing ecarcity of timber, experimenters and inveators appear to he constantly at work devising ways and means for preserving it from decay when put to practical nse. The latest improvement in this direction is that introduced hy Mr. C. Rene, pianoforte maker, of Stettin, Germaay, who ntilizes the property of oxygea, particularly of that modified hy the electric curreat, to produce tho desired result. It is very well known that wood seasoaed for years is much more suitahlo for all parpoees than if used eoon after it ie thoroughly dried. Several artificial means of seasoniag have been iatroduced, hut no syetem at preseat appeare to he largely adopted; and if a cheep and eimple process were discovered, it would ao donht tend to improve woodwork geaerally, whicb is now too often finished in a defective menner, owing to the damp etate of the timher used. This is often noticeahle in the doore aad windowe of newly built houses. Mr. Reae introducee his process particularly for musical instrnments, though there seems no reaeon why it should not he used for maay other purposes also. Instruments thns treated are said to possess a remarkably fine toae, and are not likely to deteriorate, hnt improve with age, ae did the famous violine of the old Italian masters.

A New Wood-Preserving Process has heen invented in France hy M. Jecques. He first impregaates the timher thoroughly with a eimple solution of soap, mixed with aa acid—preferably phenic acid. This causes the fermentatioa, in a few days, within the wood, of a fatty acid, which is ineoluhle ia water, aad impregnates the remotest fihere. The reaction of the acid on the soap does not take place until a portion of the water has evaporated. It is claimed that more perfect impregaation can he had in this way than with creosote, and that there is no daager of the washing out of the preservative from the exposed sorfaces, as when sulphate of copper is used. The Government Commission on technical railroad operation in France is said to favor this process.

Under-water Lamps.—A new method of illumiaatiag the taaks at the Royal Aquarinm, Westminaeter, was lately ehown hy meaas of the "Faure" electric hattery, and whicb, so far as it went, was of a successful character. The lights shown were, to the number of eix, submerged in the tank with excellent effect, showing up every fish and plant with great dietinctnoss, a result impoesihle to attain under the old eyetem of gae illumiaation. One of the great advantagee of the electric over the gas lightiag system is, that the fish do not seem to mind in the least the close proximity of the incandoscsat lamps, while at the same time they do not euffer from the noxious emanatione evolved duriag the combustion of gae.

The cracks in common mortars and cements are due, accordiag to the investigations made hy M. Decourneau, to the uncombined quicklime which they contain. In order to neutralize the lime aad overcome the difficnlty, he employs a compound formed hy mixing very fiae silicious powder with the diluted nitric acid. By thie means, mortar is obtaiaed haviag a much greater as well as more uniform and lasting resistance than those hitherto in use. The application of this method, it is stated, has givea excelleat reeults, especially in the aew forts at Parie, and the stones mede hy such process may he sawed and chiseled like natnral stone.

Spiders Obstruct the Telegraph.—Oae of the chief hinderaacee to telegraphing in Japan is the grounding of the current hy epider lines. The trees hordering the highways ewarm with spidere, which epiu their wehs everywhere hetween the earth, wires, posts, insulators, and trees. When the spider wehe are covered with heavy dewe they become good conductors and run the meesagee to earth. The only way to remove the difficnlty is hy employing men to sweep the wiree with hruehes of hamhoo; hut ae the spidere are more numerous and persistent than the hrush neers, the difficulty remeins alwaye a serious one.

Soap Bubble Balloons.—M. Delon, of Parie, producee miniatnre halloons hy means of ordinary gas conducted through a caontchouc tube aad clay pipe to glycerine soap solution. A small disk of thin paper, with fine wire from its center to a little paper car with æronaut figures, is connected to the huhhle when it hegiae to swell, the disk heiag attached hy capillarity to the part where the drop forms. The detached hubhle riece with ite car.

To Prevent Frost on Windows.—A British Colamhia eubscriher inquired leet week how he could prevent ice forming on the ineide of hie windowe in cold weather. A druggist of thie city eaye if saucere or other ehallow veeeele, ocntaiaiag eulphuric acid, are placed in varione placee in the room, the acid will absorh nearly or quite all the moieture from the atmosphere, leaving none to condenee upon the windowe.

To protect lead pipe from the action of water, form on the ineide eurface an insoluhle eulphide of lead, hy filling the pipe with a warm and concentrated eolution of eulphide of potassium or eodium. In 15 minutee pour out the eolntion and allow the pipe to dry.

Hard Putty.—The *Carriage Monthly* gives the followiag for a hard putty that will dry in one day: Take the whiteaiag, mash all the lumps out on tho stone, and mix it into a stiff paste hy addiag eqaal parts of japan aad rnhhing varaish; then add as much ksg-lead aad yon thiak will mako it work free with the knife; then add the rest of the whiteniug until you have it to suit yoa. This will saud-paper good with one day's drying. If you waat putty that will dry quicker, take dry white lead aad mix with equal parte of japaa and varoish, to whicb add a few drope of turpeatine. Thie is very soft for potty, hut caa be saad-papored in from two to three hours, it hecoming perfectly hard in that time.—*The Leffell Mechanical News.*

Brakemen.—It is rare to read a newspaper through without seeing a notice of the death of a brakeman. It is eetimated that at leest ten brakemen are killed in this country every day; that three times ae meny are iajured. They are killed or maimed while coupliag or uncoupling cars in makiag up trains, or slip on the track and are run over, or are knocked from the tope of cars, or crushed hy collieions. An occupation in which 3,650 lives are lost and 14,600 pereons incur serious iajnries, in this country alone, may well he called a dangerone one. The casualties among hrakemen appear to he much greater than among the soldiere in onr regular ermy.

To Bore Holes in Porcelain.—It is sometimee aeceseary to bore oae or more holes in porcelaia, hut the ueual way of doiag this is not easy. If, however, an ordiaary drill he hardened and kept moist with oil of turpentine, it will easily penetrate the porcelain. The drill commonly employed in connection with scroll-cutting machines answers very well.

Chamois Skins.—Maay persons suppose that chamois ekias are derived from the animal named the chamoie. In fact, the skias so called are the flesh side of sheep skins, soaked ia lime water and aleo in a solution of sulphuric acid. Fieh oil ie poured over them, and they are then carefully washed in a eolution of potash.

Mineral Oil Lubricants.—It is asserted tbat mineral oils are aot to be recommeaded as lubricants, since they attack any India rubber with which they may happen to come in contact.

Finely powdered glaee, mixed with soluhle eilicate of eoda will ho found to meke an excellent acid-proof cement.

Good Health.

Peculiar Eyes.

White hair and pink eyes are the peculiarities of the two children of Mr. and Mre. Franklin Rix, of Franklin towaship, Polk county, Iowa. One is four years old and the other two. While they are compelled to weer goggles because they caanot hear the sunlight, they can see in the dark even hetter than in the day time, being ahle to pick up a pin on the darkest night.

A Hartford (Coan.), paper relatee a singuler circumstance connected with the eyes of a young lady 16 years old, residing in Litchfield. She was recently confined for a few days in a dark room on acconnt of her eyee, until one day, after a sudden aad peculiar seneation, they felt decidedly hetter and she was taken into the light. When ehe entered the dark room her eyes were etraight and natural; she was now cross-eyed; but the moet eiagular thing ie the asserted fact that when ehe closes the right eye ehe cau see to a dietance of eight or ten miles with the left eye, and distiaguish objects as though they were withia the ordiaary range of vieion. The distant hills appear to he brought cloeer ae if hy a teleecope. Oa the other hand, when she closes tho left aad uses the right eye for vision it appeare to he a microscope. The point of a needle looks like a hlunt piece of iron, aad so with everythiag near hy. But when hoth eyes are open they assume the cross-eyed expreseion and she eeee everything natural ae other persoae see. The report is that the girl is to he taken to New York for medical examination.

Surgery in the Middle Aoes.—Dr. Lyman, writing in the *Popular Science Monthly*, refere to the low condition of surgery when it was in the haads of the harhere, and when eurgeoas were called "ekinnere." He quotes a paeeage from Sprengel, eaying that in Germany no artiean would employ a youag man as an aprentice without a certificate that he was horn in marriage of hoaeet parents and came of a family in which were found ueither harhere, hathere nor ekinners.

Acid burns.—The *Bulletin de Therapeutique* eaye that acid hurns can he cured hy the application of a eoft paete of calcined magneeia and water, in a layer ahout two millimetere in thickneee. The magnesia requires to he renewed in 24 houre; hut patients, after recovery, retain no marke of the accident

Carbuncles.—It ie recommended to treat carhunclee and hoila with pure carholic acid, injeoted hypodermioally in sufficient quantitiee to thoroughly saturate the swelling.

Whiat is Pepsin?—The *Scientific American* aaswers tho qnestion as follows: "Pepsin ie a aitrogenous substance existing in the gastric juice, and as a viscid matter in tbo peptic glaad aad on the walls of the stomache of aaimals. The mucoae membrane of the stomach (of tho hog, sheep or calf, killed fastiag) is scraped, and macerated in cold water for 12 houre; the pepsin in the etrained liquid is theu precipitated by acetate of lead, the deposit washed once or twice hy decantatiou, sulphureted hydrogen paeeed through the mixture of tbo deposit with a little water to remove the whole of tho lead, aad the filtered liqoid evaporated to dryness at a temperature not exceediag 105° Fah. As met with in pharmacy the streagth of pepsio varies greatly. It is often prepared hy simply mixing witb etarch the thick liquid ohtaiaed on maceratiag the scraped stomach with water, and evaporating to dryness. The composition of pepsin is not positively known."

Sixty-five Days in a Bath Tub.—Dr. D. Prince in the St. Louis *Med. and Surg. Journal*, describee tho treatmeat of a case of rheumatism with necrosie of the femur, bed sores aud great emaciation. He was euspended in water hy meaas of straps eo as to be completely submerged except his head, and kept in this condition 65 days aad nights. He screamed witb pain if taken out, bnt was comfortable ia the water. Some improvemeat took place, particularly in tbe soree, which were partially healed, aad though bigh hopes of a cure were excited, he died at the end of 65 daye from oxheustioa. Two grains of quinine were given daily, and two quarts of ealt put in the water, which was renewed daily, hesidee whenever defacatioa or nriaation occurred, hut etraoge to say the temperature of the water is not mentioned.

Expectancy of Life.—Insarance companiee are aware of the iacredulous weakness of those whose lives they aeeure, and have therefore compiled nnmerous tablee of expectaacy of life for their own guidance, which are carefnlly referred to hefore a policy ie granted. These tahles have heen the result of careful calculation, aod seldom prove misleading. Of course, sudden aad prematuro deaths, ae well ae livee unusually extended, occasionally occur, hut the average expectancy of life of an ordinary man or woman is as follows: A person 1 year old mey expect to live 39 yeare longer; of 10 years, 51; of 20 years, 41; of 30 years, 34; of 40 years, 28; of 50 yeare, 21; of 60 years, 14; of 70 years, 9; of 80 years, 4.

The Japanese.—The Japaaese have much to learn concerning health and disease. If we may credit the statemcnt of the New York *Herald*, they do not helieve in such a thiag as contagion, and would he as willing to live in a houee with a friend who had even so virulent a disease as the small pox, as if he were eound and in perfect health. Thus, when cholera is declared hy the hoard of foroiga physicians to he an epidemic in Yokahama, and the Japaaese goverament, at their instigatioo, take measures to prevent the spread of the diecase, the aatives object to he placed ia quarantine, and use every method in their powor to escape from their houses.

Death Caused by News of Death.—The death of the Preeident caused the death of two pereons in the town of Flint, Michigaa. Oae, a carpenter, who had worked as usual during the day, and to all appearances was in good health. He heard the hell tolled and exclaimed: "Tho Preeident is dead," aad died almost instantly. The other, a young lady who bad heen sick for some time, said, when ehe heard the bells, "The Preeident is dead and I shall eoon he with him," and died before the hells ceased tolling.

Intellectual Work on the Circulation. What are the effects of different kinds of iatellectual work on the cerebral circulation? This question M. Gley, a French physiologist, has attempted to aaswer hy experiments made upon himself. When he applied himself to a snhject which he had a difficulty in underetandiag thoroughly, and had, therefore, to concentrate all hie energiee upon it, the rythm of the heart was far more accelerated than when he took up some matter with which he was well acquainted.

Calomel in the Human System.—Considerahle donht bas heea expressed whether calomel is or ie not liable to decomposition in the human system, with production of corrosive suhlimate. According to experimente described hy P. Hoglan (*Chem. News*) calomelis slowly changed hy the action of water at the temperature of the hody with formation of corrosive suhlimate; and this chaage is accelerated hy the preeence of citric acid, eodium chloride, or sugar.

Marriages Between Relatives.—A Berlin profeseor is authority for the etatement that amoag Roman Catholics who prohibit marriagee hetween pereone who are near hlood relatives, the proportion of deaf mutes is 1 in 1,000; amoag Protestants, who are leee strict, the proportion is 1 in 2,000; while amoag Jewe, who encourage iatermarriage hetween hlood relatives, the deaf mutes are as 1 in 400.

The Preecott *Miner* eaye: The numher of deeperate characters that now infeet the San Francieco and Bill Williams ooaatiee, Arizona, make it diesgreeable and even a little dangerous for hueinese men to pnrsue their vocations in that section of oonntry.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Application of Standard Measures to Industrial Processes, 281. Passing Events; Removal; The Debris Committee; Doctors who need Doctoring; Copper Leaching. 288. Assessments; A Farm Gate; New Miner's Pick; Mining Decisions; British Columbia Mines, 289.

ILLUSTRATIONS.—Compton's Champion Farm Gate, 289.

CORRESPONDENCE.—Butte City and Mines—Montana; Camp Glencoe, Calaveras; Mining on the Klamath, 282.

MECHANICAL PROGRESS.—Mechanical Applications of Electricity; Damascus Steel; Hollow Steel Shafts for Steamships; Steam Boiler Notes; Temper of Steel; Rolling of Wire and Fine Iron; American Cars on British Railways; Heavy Plate Rolling, 283.

SCIENTIFIC PROGRESS.—Interesting Mineral Discoveries in Arizona; Supposed New Species of Horse; Casting of Delicate Nautical Objects; The Comet as Seen From a Balloon; Progress in Practical Science; A Remarkable Comet; The Electric Light on Health; Converting Power of the Potato, 283.

THE ENGINEER.—Improving the San Joaquin; The Panama Canal Scheme; Storage of Power; Underground Telegraphs; Ocean Wave Power; The Proposed Tunnel Under the St. Lawrence, 287.

USEFUL INFORMATION.—Seasoning Timber; Under-Water Lamps; Spiders Obstruct the Telegraph; Soap Bubble Baloons; To Prevent Frost on Windows; Hard Putty; Brakemen; To Bore Holes in Porcelain; Chamois Skins; Mineral Oil Lubricants, 287.

GOOD HEALTH.—Peculiar Eyes; Surgery in the Middle Ages; Acid Burns; Carbuncles; What is Pepsin? Sixty-five Days in a Bath Tub; Expectancy of Life; The Japanese; Death Caused by News of Death; Intellectual Work on the Circulation; Calomel in the Human System; Marriages Between Relatives, 287.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meeting and Dividends, 284.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana, Colorado, Utah and British Columbia, 284-85.

Business Announcements.

Goodyear Rubber Co.—Pease & Runyon, Agents, S. F.
Muley Saw Mill—Chandler & Taylor, Indianapolis, Ind.
Interest in Mine for Sale—G. W. Kling, Amador City, Cal.
Wanted! Mining Properties—Hale & Co., S. F.

Passing Events.

As will be seen by what is said in another column, the citizen's committee which has been examining the debris region, has returned, having finished its labors.

New and valuable silver mines have been discovered on the head of Clark's Fork, a tributary of the Yellowstone river, Montana Territory. The mines are located near the National park, and are on the Crow Indians' reservation. Silver was found in Clark's park as early as 1868, by three prospectors, but they were driven off by the Indians. The district is extensive, and the quantity of ore inexhaustible. The mines are located in a sterile region, difficult of access, at an elevation of 10,000 ft. above sea level, and surrounded by mountains.

There is great excitement in Tucson (A. T.), over the failure and assignment of Lord & Williams. This failure embraces Lord & Williams, a company which, in addition to C. H. Lord and W. W. Williams, includes C. E. Harlow. The assignee is H. B. Cullum, the cashier. No information can be elicited as to the liabilities or assets. It is estimated that the unsecured liabilities are not less than a quarter of a million, while the assets are merely nominal.

Strikes are reported in Eureka district, Nevada, which are said to be extremely valuable.

The Woodworth (sometimes called the Ophir) mill, Carson river, started up last Monday. It is running on tailings, of which they have on hand a deposit of 400,000 to 500,000 tons. An increase of water in the river, due more to diminished evaporation than anything else, has allowed of the starting up of the mill.

Removal.

The building, No. 202 Sansome street, in which our business offices have been situated for four and a half years, is to be reconstructed, and the removal of our business to other quarters was a necessity. We have chosen to go to the new building upon the northeast corner of Front and Market streets, where we have secured ample space for comfortable and well-lighted offices. The situation is near to the seat of the great wholesale trade in produce and manufacture; to the manufactories of implements and machines, and to the main avennes of travel and transportation. The move will, we trust, make our establishment more accessible than before to our friends and patrons, and by giving us more space for the transaction of our growing business, may enable us to work even more efficiently for the benefit of our patrons and the public interest.

The diagram of streets, which appears elsewhere in this issue, will show plainly our new location. We shall have better means of access and egress than we have heretofore enjoyed, as the stairway at 252 Market street and the elevator, No. 12 Front street, both communicate with our office. Our elevator is propelled by water power, and made specially safe. We shall be pleased to see all old friends and hosts of new ones, and to give them a full welcome.

Visitors are advised to ascend by the elevator, and then take their choice of ways in descending.

The Debris Committee.

As it is impossible for us in the limited space at command to give any extended account of the trip of the Debris Committee to the "slickens region," we will not attempt to do so. Suffice it to say, the gentlemen of the committee have visited the mining regions and the agricultural regions affected by the question, and have examined the subject as well as it was possible to do under the circumstances. Of course no thorough investigation could be made, nor are the gentlemen composing the committee conversant enough with engineering problems to offer any very learned disquisition on the subject.

They have, however, seen the dams, the farms, the mines, the debris, the rivers, the towns and the people, and they have been the recipients of the conflicting opinions of several hundred interested parties. Now that they have returned fresh from the scene of the conflict, they can and will make up a report which will at least call more careful attention to the momentous question. As the Grass Valley *Tidings* very aptly says: "The committee will look at the situation, as it is involved in the slickens question, and will give an opinion concerning it—an opinion of business men who are engaged in commercial pursuits. The opinion will not be a decision, and will not be accepted as solving the question by either party to the controversy. The opinion will not stop the litigation of the cases pending, nor will it do away with the bitterness of feeling that now exists between the opposing interests. The attention of Congress and of the nation may by that opinion be called to the matter, and the result be a system inaugurated which will protect all rights and interests, and be satisfactory to most of the miners and farmers. That is about all that can be hoped from the discoveries the Chamber of Commerce Committee will make."

There is one very apparent thing, however, in this investigation: The committee found that the mining interests up in the region visited are very much larger than they had any idea of. And they found that the money invested in these mines, and the yield from them is larger than they ever supposed. The papers which have been be-littling the mining industry by misrepresentation will not possess the influence on this question that they have heretofore enjoyed.

Another thing, too, it is seen when the representatives of the opposing interests meet together without intriguing lawyers, they both manifest a disposition to come to an amicable agreement, which must be very unpleasant to the said lawyers. It is evident if no other good has been accomplished by this committee, that this at least has been done—bringing the representatives together in friendly discussion.

The report of the committee will no doubt set before the public, in a clear, popular manner, all the facts in the case, and we await its appearance with interest.

A GLANCE at *Disturnell's Gazetteer*, of Arizona, reveals the fact that the Territory has 55 stamp mills, of from 2 to 80 stamps each, aggregating 585 stamps. Of the entire number only one mill is run by water power. Cochise county, has 9 mills, aggregating 145 stamps. Gila county, 12 mills, 79 stamps; Maricopa county, 3 mills, 95 stamps; Mohave county, 7 mills, 90 stamps; Pima county, 5 mills, 52 stamps; Pinal county, 4 mills, 37 stamps; Yavapai county, 15 mills, 117 stamps. The Vulture mill, Maricopa county, heads the list, with 80 stamps.

Doctors Who Need Doctoring.

In a late number of the PRESS there appeared an extract from a letter of one, Dr. Granville, published not long since in an Eastern paper, and in which letter the utility of the efforts now being made to improve the sanitary conditions of mankind are seriously questioned. Our object in making room for this extract being to subsequently condemn the pernicious views set forth therein.

That these views are exceedingly objectionable, may be inferred from the fact that this so-called "doctor" expresses the opinion that people lived happier and better lives before so much attention was being paid to these questions of health, than at present. In other words, this person holds to the doctrine of the sybarite, that a short life and a merry one is the most noble and desirable. He affects to doubt whether all this bother about preserving health and prolonging human life pays in the end, as if temperance, cleanliness and strict attention to other hygienic requirements taxed our time, and means any more than the neglect of these laws, giving loose rein to our appetites and freely indulging in luxury and pleasure—as if it were not as easy to live right as to live wrong.

As the chief aim of these health preservative and restorative efforts consists in securing better ventilation and sewerage, the use of more wholesome food and purer water, the taking of more physical exercise by those who need it, exposure to sunlight, proper methods of clothing, personal cleanliness, abstinence from liquor, tobacco, opium and other expensive excitants and narcotics, it is hard to see how these aims, if fully carried out, are going to greatly increase the burdens of society or add to the sum total of human unhappiness. If, as this medico asserts, mankind were better and happier in times past, when they less concerned themselves about sanitary matters, it was because they then made little use of these pernicious articles that are now working so much harm, and towards effecting the disuse of which these reformatory measures are mainly directed. These disciples of the sensual school forget that the benefits that come of an advanced civilization are nearly counteracted by the evils that accompany them. To profit by the new, we must retain something of the simplicity that attended the old. If the log cabin was rude and uncomfortable, it was self-ventilating. If food in more primitive times was simple and coarse, it was little adulterated. If liquor was drunk, it was distilled from corn and rye and not compounded from deadly drugs, as at present. It is only two or three centuries since tea and tobacco were introduced into Europe, and hardly more than half a century since coffee came into general use. And now that we are threatened with a new evil, the use of opium in its various forms, it would be in accordance with the logic of these *laissez faire* philosophers to let the habit grow, and, abstaining from all repressive measures, allow the accursed drug to have full sweep.

The victim of this degrading habit delights in the sensation produced. Why interfere with his enjoyments or seek to check the practice by repressive measures and sumptuary laws? Why, in fact, trouble ourselves about the welfare of any human being, or even our own? "Soul, take thine ease; eat, drink and be merry, for to-morrow thou shalt die," is the language of the modern, as it was of the ancient fool. What signifies that crimes and intemperance increase; that self-murders multiply and lunacy grows apace? What cares this sort of doctor about the declension of virtue or the deterioration of the human race? What has he to do with the strong, well-preserved and healthy? It is only the weak, infirm and flabby that can be of any use to him.

And he has many followers, this man who so encourages the spread of disease that he may have a chance to cure it. All the vast army of sensualists, the slaves of appetite everywhere, preach this same doctrine of unrestrained indulgence in practices that they well know impair both their mental and physical vigor and lead to premature death. But it avails little to talk to them; the chains with which appetite binds its captive are generally too strong to be broken by appeals to interest, duty or reason.

We do not charge that this man sins against light. He evidently belongs to the blind leaders of the blind—that class of physicians who have never been hygienically enlightened. That all such men, however they may be dubbed "M. Ds." tend to bring the healing art into disrepute and scandalize the noble profession to which they belong, admits of no question.

THE practice of duplicating the names of mining companies or adopting the titles of existing companies is to be deprecated, and we can see no good reason why a company should so far loose sight of honorable dealing as to persist in the practice. A similarity of names leads to confusion, and so far as mining is concerned, has a tendency to destroy confidence. All such efforts are unworthy of credit, and the company adopting this plan of enticing the public should receive the wholesale denunciation it justly merits.

LAST week the police at Frankfort-on-the-Main seized and confiscated all the posters and bills in restaurants, which gave information to those intending to emigrate to America.

Copper Leaching.

Some time ago, in one of a series of articles on this subject, an outline was given of the Hunt & Douglass process of treating copper ores, by which silver, if present, is also extracted. The process was considered to be the best copper-leaching process then known. One of its advantages is that two-thirds of the copper is extracted in the form of dichloride, from which a given weight of iron precipitates twice as much copper as from a solution of protochloride or sulphate; the other third of the copper is protochloride. Thus, the consumption of iron is reduced to two-thirds of the quantity required by other processes; that is theoretically, but in practice to a still smaller proportion, owing to the absence of persalts of iron, which are usually formed in the other processes. Moreover, by passing the solution over sulphids of copper, the protochloride of copper in the solution is converted into dichloride by taking up another atom of copper, and by this means the consumption of iron is reduced, practically, to one-third of that of the older methods. Silver, if present, is dissolved as chloride, and may be recovered by precipitation on metallic copper, at the ultimate expense of the further portion of iron required for the precipitation of the copper thus dissolved.

Notwithstanding its merits, this process has certain defects. In the first place the reaction by which the copper is dissolved through the agency of protochloride of iron, causes the formation of hydrated peroxide of iron, a substance which greatly obstructs filtration, and from which, when filtration is replaced by decantation, it is still difficult to wash the solution of copper. In the second place, if silver is present, it cannot be precipitated from the solution by metallic copper, until the whole of the dissolved copper is reduced to the state of dichloride, and although the ultimate consumption of iron is not increased from this cause, since that consumption is determined by the quantity of chlorine to be saturated, and not by the quantity of copper to be thrown down, yet the necessity involves a certain inconvenience from loss of time; and if the ore is rich in copper, a larger quantity of brine may be required, because the dichloride of copper is much less soluble than the protochloride. It is true that the reduction to dichloride may be effected by means of sulphide of copper as stated, and then the saving of iron may compensate the loss of time, and necessity for more brine and extra vats; but this method is not always convenient.

The method of Claudet, of separating silver from copper in a mixed solution of the chlorides of those metals, by means of a soluble iodide, which throws down iodide of silver, is not applicable in the presence of dichloride of copper, hence, cannot be used in connection with the Hunt & Douglass process. A partial separation is effected by adding to the mixed solution a certain quantity of a soluble sulphide; the whole of the silver is precipitated as sulphide, together with a portion of copper, also as sulphide. The writer has found that the metals can be almost perfectly separated by operating on a boiling solution with a soluble sulphide, until nearly the whole of the copper is thrown down; the silver remains dissolved, and may be separately precipitated either as sulphide, together with the remaining copper, or otherwise.

This result depends on the fact that sulphids of silver is converted into chloride by a hot solution of either of the copper chlorides in brine. On the same principle the copper may be removed by precipitation as oxide instead of sulphide, and with the advantage that the oxide is the more tractable in the after treatment; but in either case the consumption of material would be considerable.

In view of these difficulties, the versatile inventor of the process, Prof. T. Sterry Hunt, of Canada, has recently devised another which, for neatness and apparent efficiency, can hardly be surpassed. This process depends upon the following facts:

First, if sulphurous acid gas is injected to a solution of chloride of copper, the metal is nearly all precipitated as dichloride, while sulphuric and hydrochloric acids are formed.

$$2\,Cu\,Cl + SO_2 + HO = Cu_2\,Cl + HCl + SO_3\,.$$

Second, if sulphurous acid gas is injected to mixed solution of sulphate and chloride of copper, in equivalent proportions, the metal is nearly all precipitated as dichloride, and sulphuric acid is formed.

$$Cu\,Cl + Cu\,SO_4 + SO_2 = Cu_2\,Cl + 2\,SO_3\,.$$

Third, if dichloride of copper is exposed to air, it takes up oxygen, forming oxychloride,

$$Cu_2\,Cl - O = Cu\,Cl + Cu\,O,$$

and sulphurous acid gas converts this again into dichloride, while being itself converted into sulphuric acid.

$$Cu\,Cl\,CuO + SO_2 = Cu_2\,Cl + SO_3\,.$$

These latter reactions take place simultaneously if air and sulphuric acid gas are passed together into water in which dichloride of copper is suspended.

In all these reactions the SO_3 combines with a portion of the water, forming HSO_4, or liquid sulphuric acid. Chloride of silver is insoluble in the acid liquid and in solution of sulphate of copper.

In practice, a solution of sulphate of copper is obtained to begin with, by means that will readily suggest themselves to the metallurgist, such as leaching some roasted sulphurous ore, or treating some oxidized ore with dilute

sulphuric acid. To this is added a quantity of a soluble chloride, such as common salt, equal to a little more than half the equivalent of the sulphate of copper in the solution, producing a mixture of sulphate of soda, chloride of copper and sulphate of copper in nearly equivalent proportions.

$2\,Cu\,SO_4 + Na\,Cl = Cu\,Cl + Cu\,SO_4 + Na\,SO_4$.

Sulphurous acid gas is then injected, and reaction No. 2, as above, takes place, nearly all the copper being thrown down as dichloride. Any excess of sulphurous acid in the liquid is now oxidized by the addition of a portion of the original solution reserved for this purpose, the dichloride is allowed to settle, and the acid liquid, which retains a little copper in solution, is used to dissolve the copper out of artificially or naturally oxidized copper ore.

If silver is present, the small quantity of chloride of copper in the liquid suffices to convert it into chloride, but not to dissolve it. It, therefore, remains in the insoluble residue, together with gold in the metallic state, and lead, if present, as sulphate, all or either of which metals may be afterward extracted by various well-known means, as smelting, leaching or amalgamating. The liquid is drawn off and treated with a soluble chloride, and with sulphurous acid, as before, and so on continuously.

The oxides of zinc, nickel and cobalt, if present in the ore, are dissolved together with the copper, but are not precipitated by sulphurous acid. They therefore accumulate in the liquid, and may be recovered from time to time by appropriate treatment.

If no silver exists in the ore, it is immaterial whether the half, or the whole of the sulphate of copper in the liquid is chlorodized by adding salt, etc., the only difference being that in the latter case, hydrochloric as well as sulphuric acid is produced, as in reaction No. 1; consequently chloride of copper is formed, as well as sulphate when the liquid is applied to another lot of ore. Chloride of copper dissolves chloride of silver, and is therefore objectionable when silver is present, because a portion of the latter would be carried down with the dichloride of copper in the subsequent precipitation by sulphurous acid. But in no case should a large excess of salt be used, as it increases the solubility of the dichloride of copper.

The precipitated dichloride of copper is collected and washed. It may then be reduced to pure copper by placing pieces of iron in it, while keeping it covered with water to prevent access of air, and to dissolve the chloride of iron formed; $Cu_2\,Cl_2 + Fe = 2\,Cu + Fe\,Cl_2$. The solution of chloride of iron may be used in place of salt, to add to the next solution of sulphate of copper. If iron cannot be had conveniently, the dichloride may be converted into suboxide of copper by boiling it in water with lime.

$Cu_2\,Cl_2 + Ca\,O = Cu_2\,O + Ca\,Cl_2$.

The suboxide is easily smelted to fine copper, and the chloride of calcium may be used in place of salt to add to the solutions, but in this case insoluble sulphate of lime will be formed, and must be allowed to settle and the liquid removed to another vat, before precipitating the copper by sulphurous acid.

If sulphureted ores or mattes are treated, they must first be oxidized by roasting, and the sulphurous acid evolved may be utilized for the precipitation. In this case a certain quantity of sulphate of copper is formed in the roasting of the ore, and in consequence, the quantity of acid in the liquid increases with each operation, so that after a time, it may be necessary or convenient to throw away a part of the liquid. Before doing so, any copper which may remain in solution, after the treatment with sulphurous acid, is precipitated by metallic iron.

When naturally oxidized ores are treated, the sulphurous acid must be obtained in some other way, as it cannot be produced from the ore itself. In this class of ores it may happen that lime, magnesia, or metal oxides other than copper may be present, which consume the acid of the liquid, and then it is necessary to increase the quantity of acid, which is done according to reaction No. 3, by injecting air together with the sulphurous acid into the solution.

The advantages of this process over the original Hunt & Douglass process are, firstly: silver if present, is not dissolved together with copper; secondly, there is no formation of peroxide of iron to obstruct filtration, etc.; thirdly, the copper is obtained in great purity, and with the least possible consumption of iron or of lime; less than 50 lbs. of iron being required for the production of 100 lbs. of copper. On the other hand, it has the disadvantage of requiring a considerable quantity of sulphurous acid, which, if not furnished by the ore itself may not be conveniently obtained. Sulphurous acid is also used in the former Hunt & Douglass process, but not in such quantity, and only as an adjunct which is not always indispensable.

We respectfully call attention of such of our readers, or anybody else, who would be desirous of manifesting an interest in operating a mine, to the advertisement of the "Eclipse gold quartz mining company" in another part of this paper. It adjoins immediately on the north the celebrated Keystone mine, which is hard by in the south. The right of claim is protected by a United States patent.

The Sierra Nevada and Utah mines will presently be connected on the 2500 level. When this is done one may start from the latter mine and travel underground over a mile to the southward from mine to mine.

Assessments.

The fact that assessments are levied on the stock of Comstock mines, seems to worry some of the Eastern mining stock papers considerably. They are continually harping upon the fact that about $70,000,000 have been put into the Cometock in the shape of assessments; but they do not say very much about the $320,000,000 yield or the $112,000,000 dividends from the same mines. California and Con. Virginia, between them, produced nearly $130,000,000, or almost double all the assessments levied on all the mines on the whole lode.

One paper is astonished particularly at the assessment paying, and says: "Neither benevolence, patriotism nor encouragement of home industries seems to be the aim of the constant assessment payer. He seems to be laboring under a hallucination for which materia medica prescribes no cure—the craving for a bonanza."

There is a good deal of "general principle" twaddle going the rounds, originating from Eastern papers, on this subject. When people go into mining they always expect a bonanza. If they do not look for a bonanza in the mine they do for one in the stock. When they put money into stock they expect to sell for a higher price or to get dividends. If no dividends come, and stock does not go up, they try to make a "boom." If the boom slips up they try and sell out for what they can get without reference to the result to the buyer. This is not only human nature, but what the world calls business.

In the matter of assessments, if people expect that the mine will pay, they are willing to pay themselves to put it in shape to do so. Shafts do not sink, drifts run or tunnels extend without muscle or brains, and muscle and brains want money. If people didn't think they'd make something out of it they wouldn't invest. They don't invest for the privilege of paying assessments, as one would suppose from reading some Eastern journals. But when assessments are levied, if people think they have a chance of making something out of the mine or a subsequent rise in stock, or they think they can save part of a bad investment, they pay; otherwise they do not. It is purely a business proposition, the chances of which are taken when the first investment is made.

All the sympathy expended on assessment payers is wasted. In regard to the Comstock, work done as the result of assessments has developed bonanzas in a number of the mines, and those who pay assessments now, hope for the experience to be repeated. They are not trying new experiments. They are doing something that has been done before. Some of the experience has resulted in bonanzas, and some in horrascas. Those who met the boracas lost only their small investments; those who struck bonanzas gained in some cases a thousand-fold on their investment.

These circumstances make men invest in a region where bonanzas may be uncovered any time, and make them pay unwelcome assessments more readily than might be imagined. All the advice given them will not change their minds, and this is more particularly the case where the newspapers offering it, give aid and countenance to obscure stock for sale in unknown regions where bonanzas are unheard of, real mines never seen, 50-ft. shafts the rule and dividends the exception. None of the Cometock mines have any prospectuses to publish in these journals, or any kind of advertisements to insert; and when one sees these mines, which have produced millions, and are fully equipped for work, on a lead where bonanzas may be found anywhere, constantly maligned, while others, which have not machinery, shafts, ledge, or anything but stock, but which publish page prospectuses and flaming advertisements, as constantly held up as models for investment, the thinking man is apt to conclude that advice from such sources is not entirely disinterested.

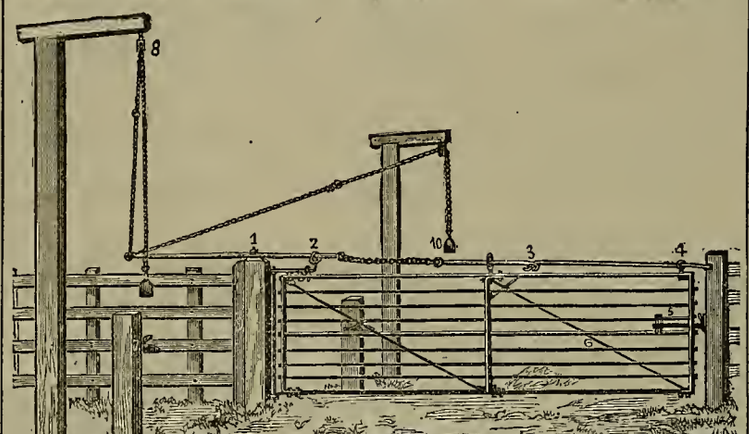
A gradual reduction in the custom tariff is proposed in Spain.

A New Farm Gate.

The engraving on this page represents a new farm gate invented by Alfonzo P. Campton, of Rohnerville, Humboldt county, California, and which is taking well wherever introduced. The principal features of the invention is the horizontal lever hinge pivoted on top of the upper rail of the gate, this lever hinge being provided with an eye or loop, through which is passed the front end of a horizontal lever, which is pivoted on the top of the gate-hinge post, and has its forward end attached to a sliding latch. Suitable cords are attached to this horizontal lever, and these loose ends led to the proper position to be grasped by a person on horseback or in a vehicle.

The operator, on horseback or in a vehicle, approaching the gate, pulls the cord marked 10 in the engraving, thereby moving the lever, 1, laterally on its pivot. This lever, 1, then presses sidewise in the eye or loop, 2, moves the hinge of which this eye or loop forms part on its pivot, with the effect of drawing taut on the chain, whereby the gate is inclined from its vertical plane and raised on its lower hinge or pintle, and by the same means the latch, 3, is drawn from the catch, 4, while the swing of the same gate also liberates the catch, 5. A continuous pull upon the cord, 10, throws the gate open against one of the catches, 7. After passing through the gateway the operator will pull the opposite cord with the effect of releasing the gate from the catch and restoring it to its primary condition. The cords are led through pulleys, 8, on suitable posts so as to be in convenient position.

The latch used on this gate is such that it cannot be raised by cattle, hogs, or other animals. The corner post, 9, is firmly planted in the ground, so as to sustain the gate without



CAMPTON'S CHAMPION FARM GATE.

allowing it to sag. The gate is preferably made of iron. This gate took the first premium this year at the California State fair, the Stockton fair, the San Jose fair and the Ninth District fair, in Humboldt county. The inventor desires to sell State and county rights. Quite a number of gates of this pattern are in use, some of them being even sent to Mexico. Mr. Campton calls it the "Champion gate."

New Miner's Pick.

P. W. Reardon, of San Jose, has just secured through the Mining and Scientific Press Patent Agency a patent for a mining or grading pick of new design, the principal feature being a novel means of adjusting points to the head or stock so that the points can be removed when worn or injured and others substituted.

The shape of the stock is such as to leave shoulders upon its outer side. In its ends are beveled sockets. From the bottom of the sockets extend inclined tapering holes, which open out at the shoulders.

The pick point has an ordinary curved point or blade. Its rear end is cut away to form a beveled projection, from which extends a tapering shank or stem. The end of the shank is provided with screw threads, and is adapted to receive a nut.

When the point is fitted to the stock, the shank extends through the hole and projects on the outer side at the shoulder. The beveled projection fits within the beveled socket, and the shoulder of the point which is formed by the projection, fits against the end of the stock. When the point is well in place, a nut is screwed onto the end of the shank, and when set up tight against the shoulder, holds the pick point and the beveled projection. When a blow is struck, the point has a tendency to be driven in further and held more securely. The loosely-tapering stem or shank is also tightened by drawing, and holds the point in place, and the nut can be tightened to the extent of the strength of the screw threads. The device is quite simple. The removal of the nut allows the point to be taken out with ease, and can be inserted again with facility.

Mining Decision.

The Supreme Court at Yankton, Dakota, has confirmed the decision of the U. S. District Court of the Territory in the case of Mahler vs. Golden Terra Mining Co., in favor of the plaintiffs. The District Court decision was published in the law journals of this city at the time, and favorably commented upon. This confirmatory decision is the final judgment in favor of the Gopher Con. G. M. Co., the suit for which was fought by the Gopher interest against the Golden Terra company, the principal owners of which were Messrs. Haggin & Hearst.

The attorneys in the case were Garber & Thornton and McLaughlin & Steele for plaintiffs, and Hillhouse, Corson & Thomas for defendants—Golden Terra Co.

It is generally understood that the control of the Gopher stock was purchased by Mr. Haggin after the case was decided by the District Court. In view then of this recent decision, which confirms the former one, which absolutely invalidates the Ophir title, and the fact that a suit for heavy damages against the Golden Terra would inevitably follow, instituted by the Gopher company for ores extracted from their ground by said corporation, the purchase of the majority of the Gopher stock was a wise business transaction.

The ground covered by this decision has always been regarded as the richest portion of the main vein, extending from the Homestake mine on the south to the Father De Smet on the north. The hotly contested suit for the ownership of this ground and subsequent purchase of the control of the Gopher stock, is conclusive evidence of the great value of this property. The stockholders in the Gopher company are to be congratulated on this recent decision, and under the able management of Messrs. Haggin & Hearst this mine should soon take a place among those paying dividends.

British Columbia Mines.

We had an opportunity of conversing this week with Major Downie of Nevada City, who has just returned from a prospecting expedition on the northern coast. He left here last April, going by steamer to Victoria, and then to Bellahella. Taking a canoe and some Indians, he has explored a great deal of the British Columbia coast, examining some galena and silver lodes he knew of. Where he expected to find his best ledges, he says the ground was covered up with snowslides and slides from the mountains.

He says that he found good prospects of galena at different points on the coast. He aimed, however, to find those near to the water and easy of access.

At the head of Donglas inlet he found silver ore running $35.68 per ton, the lead being well defined and some seven or eight ft. wide. This was within half a mile of the water. He has found a great deal of copper ore. Douglas inlet, or Kitahmat, as it is called, is the site of a large Indian village.

Major Downie went to Fort Wrangell by steamer, and then on up the coast with the canoe. He has found two or three galena claims which he is confident will prove valuable. The Indians in that region are all peaceable, and he had no trouble with them at all, they being well disposed all along the coast.

Major Downie has showed us a great number of specimens of ore, principally copper. He has secured several good ledges for the company in whose interests he went up. He says that all along the coast new salmon fisheries are being established, and that this great industry is rapidly growing. Major Downie has promised us further particulars regarding his prospecting trip as soon as he reports to his company.

The Brush Dam Burned.—The other day when the Debris Committee went to visit the famous brush dam, the party went along the dam about one mile, over the deposit of slickene. Some persons, who must have done it through malice, had set fire at the north end of the brush dam, and it being fanned by a steady north wind, had already burned about 600 ft., and was progressing rapidly to the south. Men were sent for from the levee work below to extinguish the fire, and were busy at work at it when the committee and party left. The discovery of the fire occasioned a great deal of excitement among the representatives of the farming and mining interests who were accompanying the committee. The well-known hostility to this brush dam system among the farmers prompted some to insinuate that they knew something about the origin of the fire. Others hinted that people in the vicinity who held $60,000 worth of the State scrip issued in payment for the work and made valueless by the recent decision of the Supreme Court, might have sufficient bitterness against the projectors of the dam to want it destroyed.

The hoxing up of the hot water in the Imperial and Alpha mines, in sub-drains buried several inches below the floors of the drifts, has greatly cooled the 2800 level of those mines. Before the water was so disposed of the drifts were filled with blinding and scalding steam.

THE PIONEER
ACCIDENT COMPANY
OF AMERICA.

ONE OF THE BEST
LIFE COMPANIES
IN THE WORLD.

—THE—

TRAVELERS INSURANCE CO.,

OF HARTFORD, CONN.,

LIFE or ENDOWMENT POLICIES of all Safe and Desirable Kinds.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

A NEW TREATMENT for Consumption, Asthma, Bronchitis, Catarrh, Dyspepsia, Headache, Debility, Neuralgia, Rheumatism, *and all Chronic and Nervous Disorders.*

ACTS DIRECTLY upon the great nervous and organic centres, and *cures by a natural process of revitalization.*

HAS EFFECTED REMARKABLE CURES, which are attracting wide attention.

HAS BEEN USED BY Rt. Rev. John J. Keane, Bishop of Richmond, Va., Hon. Wm. D. Kelley, T. S. Arthur, and others, who have been largely benefited, and to whom we refer *by permission.*

IS STRONGLY ENDORSED: "We have the most unequivocal testimony to its curative power from many persons of high character and intelligence."—*Lutheran Observer.* "The cures which have been obtained by this new treatment seem more like miracles than cases of natural healing."—*Arthur's Home Magazine.* "There is no doubt as to the genuineness and positive results of this treatment."—*Boston Journal of Commerce.*

THE OXYGEN HOME TREATMENT contains two months' supply, with inhaling apparatus and full directions for use.

SENT FREE: a Treatise on Compound Oxygen, giving the history of this new discovery and a large record of most remarkable cures. Write for it. Address

ADMINISTERED BY INHALATION. Drs. STARKEY & PALEN, 1109 and 1111 Girard St., Philadelphia, Pa.

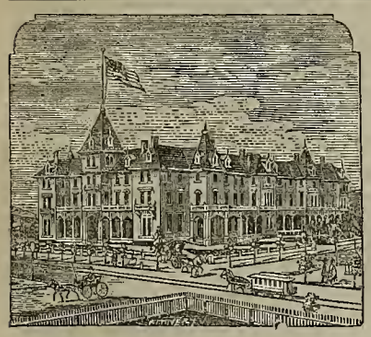
Depository on Pacific Coast.

WE HAVE ESTABLISHED A DEPOSITORY OF OUR COMPOUND OXYGEN HOME TREATMENT at San Francisco, Cal. This will enable patients on the Pacific Coast to obtain it without the heavy express charges which accrue on packages sent from Eastern States.

All orders directed to H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., will be filled on the same terms on which we fill orders sent directly to our office in Philadelphia.

Patients ordering from our depository in San Francisco, should, at the same time, write to us, and give a statement of their case, in order that we may send such advice and direction in the use of the Treatment as their special disease may seem to require.

DRS. STARKEY & PALEN, Nos. 1109 and 1111 Girard Street, Philadelphia, Pa.



TUBBS HOTEL,

East Oakland,

Having been Thoroughly Refitted and Refurnished, Painted and Frescoed, is now Open for the Reception of Guests. Rooms can now be secured at the Hotel.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

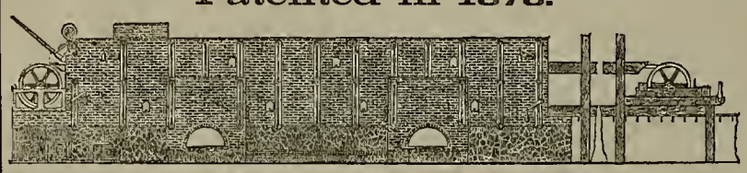
THE O'HARRA

CHLORIDIZING FURNACE.

Patented in 1878.



SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ors is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ors to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenical sulphurets of silver up to from 84% to 95% of the assay.

SHEET IRON PIPE.

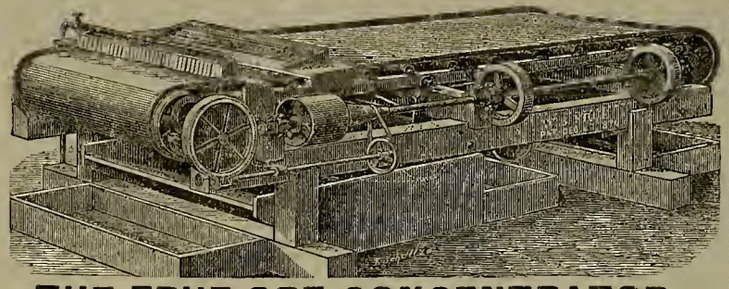
MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill. It requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies. Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.
Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.
We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.
☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.
ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Learning the Ropes.

The following from the Philadelphia *Record* shows that the Eastern folks are not guiltless of "ways that are dark and tricks that are vain:"

"The *modus operandi* by which sharpers operate in mining companies is bold, yet simple. They buy a piece of land at an insignificant sum, and arrange that the deed shall be recorded with an enormous sum named as the consideration. Then they form a stock company, with a nominal capital ranging from $2,000,000 to $10,000,000, take half of the stock themselves and lay aside the balance, ostensibly for development. A few brokers then take the concern in hand, and by what is called "washing," they sell and resell 100 shares of the stock at, say one dollar a share, making it appear that a share which does not represent one cent of invested capital is worth that sum. After the stock has become fairly floated, then come the expedients for squeezing the innocents."

Another trick was as follows:

"One company, which had a good mine, fell into the control of a crowd of sharpers, who have terrorized the puny stock lambs. It was done in this way: The company had mined some little ore, and a report was received from the mine superintendent stating that the ore dump was worth $60,000. Immediately the Board of Directors were called together to dispose of the dump. A dividend could not be declared on money not in hand, but an accommodating firm announced that it would advance funds to the amount of $60,000, taking the ore as security. It was thus made to appear that $60,000 had been mined in excess of working expenses, and a dividend of $60,000 was declared—this, of course, advancing the price of the stock from 20 cents to $1.80 per share. Then it was revealed that through an understanding among themselves the ring of directors had not taken any of the dividend, and that the accommodating firm which advanced the funds had not advanced $60,000, as supposed, but only $8,000, which went to those not in the conspiracy. The clique sold out at top prices, realizing more than enough to protect the $8,000 advanced, and the unsuspecting lambs were meanly plucked."

MEXICAN DUTY ON MINING MACHINERY.—It was stated and the impression very generally obtained some months ago that a heavy duty was to be imposed by the Government of Mexico upon all mining machinery, lumber, etc, imported into that country. Afterward it was stated that this measure, meeting with strong opposition on the part of the more intelligent and progressive element in the national Congress, failed to be enacted into a law. This latter however, appears to have been a mistake, the Phœnix *Herald* being informed by Senor Manuel M. Corrella, who recently returned from Hermosillo, where he went on business connected with mining interests of Sonora, that the law of levying an import duty upon mining machinery, lumber etc., did pass and go into effect on the 1st of November. The public ought not to be deceived on this subject, for that leads to unnecessary complications when the importer arrives at the frontier and the duties are demanded. There are already too many causes for complaint, wherefore we should labor to diminish them as far as may be by the diffusion of judicious advice and correct information.

OUR COMSTOCKERS do not think much of the majority of what are called mines down in Arizona. They say that in many instances the deposits upon which Arizona mines are incubating might be dug out and packed away on a jackass at one load. The Virginia *Enterprise* is responsible for this.

Gunpowder and the Stronger Explosives for Mining Purposes.

Following up this subject from the *Journal* of September 24th, we find there are many conflicting opinions afloat as to the relative merits of the old and time-honored explosive agent, gunpowder, and the younger, more vigorous ones, dynamite, tonite, and others more or less connected with the two last named rivals. As we have remarked before, the nature of the ground and work required will have much to do in deciding the question of merit in regard to explosives in general. Gunpowder must always hold its place in very soft ground, or where immense quantities of material have to be displaced to be utilized for special purposes, and where local action alone could not be profitably employed. It may be said to be the parent explosive, and, like all parents, has had to make way for the more robust offspring, and bear the effects of opposition and slight; these have passed away, and users are now beginning to value the several explosives agents according to the merits appertaining to each. Dynamite and tonite we have referred to as rivals; both have their adherents, and each is valued for its special advantages. The plasticity of dynamite is one of its advantages where hand boring is carried on irregularly. Tonite in many formations is said to have more displacing power, to be exempt from noxious fumes, and, unlike nitro-glycerine explosives, requires no thawing, an advantage which is without doubt appreciable. We are informed that the consumption of tonite is extending. There is evidently a wide field for both, and we should say, for all the explosives we have named in connection with work to which each is specially adapted. We are also informed that experiments on a large scale have been recently carried on in the chalk formation with a view to combining the advantages of gunpowder with tonite, and that the results have been satisfactory, the saving of time and labor, and the quantities displaced as compared with the old system, being very great. These experiments are being continued, and we hope to obtain further particulars, with a view to placing them before our readers on a future occasion.

We would wish to remark that the results of trials are often marred through want of supervision on the part of those who are most anxious to arrive at a fair result, want of time on the part of a manager, or too much reliance on the opinion of workmen, who are generally more or less biased one way or the other, too frequently result in hasty and imperfect conclusions being arrived at. It is of the highest importance, therefore, whenever an extended trial of this nature is in hand, to have the strictest supervision possible carried out, to have the charges regulated according to the work to be done, and their effect noted in each case.

Another point we would wish to remark on is the necessity of compelling workmen to attend to the instructions which accompany all explosives, it being generally admitted that miners, as a rule, are apt to disregard such instructions. They should remember that the stronger an explosive is the greater necessity for caution, irrespective of the safety of the material they are handling. This refers to all, and more especially to nitro-glycerine, explosives, when handling the latter in a frozen state, and we are now fairly launched into cold weather. The accidents which frequently take place in carelessly manipulating nitro-glycerine explosives when frozen, will justify these remarks. Immunity from accident for a time generally engenders laxity in use, and we may, therefore, be excused for thus touching on the necessity of caution, when dealing with the subject of explosives generally, and trust our remarks will be taken in good spirit, as intended.—*London Mining Journal.*

ARMAGOSA.—Says the San Bernardino *Index:* The celebrated Armagosa mine has recently been purchased by the South Pacific mining company of New York. The company intend to erect a 20-stamp mill at once and increase the number of stamps to 56 within four months after the first 20 are completed. The mine itself is wonderfully rich and well opened. Under its former management it yielded ore of enormous richness—one blast of two tons having yielded $11,000, and the 5-stamp mill $58,000 in one month. Of course the ore was selected, yet this shows the possibilities of this great mine. As many of our readers are aware, the Indians massacred the miners and burned the company's mill, which was a death-blow to the old company.

IF SATISFACTORY ARRANGEMENTS can be made with the Virginia City and Gold Hill water company the big hydraulic pump at the Chollar-Norcross-Savage shaft will be run by a stream of water turned directly into the feed column. This would do away with the surface machinery and the return column now forced up to the top of the ground. All the water would then pass out at the Sutro tunnel level and the pump would run right along almost as though by perpetual motion.

BY ADVERTISEMENT in another column it will be seen that Hale & Co. are in want of some mining property for the New York and London markets. Mr. W. E. Hale was formerly of the firm of Hale & Pacheco, brokers. Mr. Hale has been some 10 years or more in business here in this city, and is well known to the mining community.

News in Brief.

DEER are plentiful in Mendocino, Humboldt and Trinity counties.

FRANCIS A. WALKER, superintendent of the census, has resigned.

GEESE, ducks and cranes are making their appearance on the San Joaquin.

MINOR PENALTIES have been discovered in the U. S. Treasury Department.

WILD pigeons in great numbers are reported in Putah canyon, Solano county.

THE Chinese quarter of Dutch Flat was entirely destroyed by fire last week.

TWO Indian hunters lately brought a deer to Chico which weighed 168 lbs. Its antlers had seven prongs.

EDWIN D. MORGAN has been selected by President Arthur as Windom's successor, as Secretary of the Treasury.

THE relics of the Franklin expedition recovered by Lieut. Schwatka have been placed in the museum at Greenwich hospital.

CHOLERIC fever is raging at Umritsir, India. Nearly all the shops are closed. Not a single European escapes the disease.

THE sawmills at Lake Tahoe have shut down for the season, and most lumbering operations have been suspended till next spring.

THE Atlantic house and buildings on Salisbury beach, Mass., have been burned. The loss is $20,000. Insured.

LANDER COUNTY, Nev., has reduced the Central Pacific assessment from $16,000 to $10,000 per mile for main track.

RAISIN packing is progressing rapidly in Riverside valley, and three-fourths of the crop is now either packed or in sweat boxes.

THE original sum of £500,000 given by the late George Peabody in 1862, as a fund for building a lodging-house for the poor in London, now amounts to £720,000.

CAPT. HOWGATE has entered a plea of "not guilty" to the charge of embezzlement. He has been committed to jail in default of bail, fixed at $30,000.

THE American Humane Association have decided to bring into the Supreme Court of the United States a test case of the cruel treatment of stock in transit on railroads.

WITH a view to cover the deficit in the Hungarian revenues, it is proposed to introduce a tax on petroleum, revise the customs tariff and increase the tax on alcoholic spirits.

THE Piutes are bringing in wild ducks from the Sink of the Humboldt, which they peddle about Virginia City. The say wild fowl are very abundant at Humboldt and Pyramid lakes.

SHAW, United States Consul at Manchester, has visited Oldham to inquire into the grievances of mill owners regarding the alleged pressence of sand in bales of American cotton.

THE Socorro *News* says: The turquoise in the crown of Russia came from the mines of New Mexico nearly two centuries ago. It is the largest and finest stone of the kind in the world.

THE Lower Lake *Bulletin* says: Lake county abounds in mineral wealth, yet there is scarcely another portion of the State that has been so little prospected.

THE Chico *Record* says: Some days since a party of hunters on the Liano Seco ranch, broke camp, leaving their camp fire burning, and 400 or 500 acres of pasture land were burned over.

TRICKETT, the Australian oarsman, has sent a formal challenge to Hanlan to row a three-mile race on Crevecœur lake for $1,000 a side and the championship of the world, at about the end of November.

THE Cloverdale *Reveille* says that the recent free on the coast have driven a great many deer and fawn into the adjacent valleys, and the stages either bring them in or report them as numerous all along the line.

ADVICES from Panama of the 15th say: The Interoceanic Canal Company has bought the Grand hotel of this city for $206,000, and it will be converted into offices for all departments of the company.

IT IS understood that Senator Miller has prepared a bill providing for a simple form of government for Alaska, which meets the approbation of all the prominent men interested in the Territory. It simply provides for a court having general jurisdiction, for an executive officer and for a delegate in Congress.

THE movements being made on the Donahue railroad survey between Cloverdale and Ukiah, are of that positive nature that the residents of this upper country are beginning to draw long breaths. The survey between those two places is completed, and every assurance given that the work will be commenced early in the spring.

THE New York *Herald* prints another full page of Arctic correspondence, on which it editorializes as follows: Prof. John Muir thinks that the *Jeannette* pushed directly north through the long lane of open water extending at least 100 miles southward from Herald Island, looking like an open river between the banks of ice, which was frozen to the shallow bottom. The stream which flows through this opening off the east coast of Wrangell Land is said to be set northerly, at the rate of about two knots an hour, and clearly indicates an opening farther north, whence millions of young geese come. Swedish reports confirm this view of the opening, and it is highly probable that the *Jeannette* saw it and pushed as far northward as possible, which would fully account for the *Corwin's* failure to discover any trace of the *Jeannette* on the southeast coast of Wrangell Land, where alone she made any search.

Business and Patent Office Removal.

After October 29th, our friends and patrons will find the business offices of Dewey & Co. removed from No. 202 Sansome St., to No. 252 Market St., on the northeast corner of Front and Market Sts. We have secured the entire upper floor of Nos. 250 to 252 Market St., and No. 12 Front St., where we shall have permanently more spacious and pleasant rooms for the accommodation of our increasing business. Our apartments will have two main entrances as shown in the following engraving, viz:

OUR STAIRWAY, No. 252 MARKET ST.
OUR ELEVATOR, No. 12 FRONT ST.

The building we have now occupied between four and five years is to give place to a new one, which fact causes our removal.

Old and new friends are cordially invited to give us an early call in our new quarters.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies, postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 252 Market St., San Francisco, Cal.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.
B. W. CROWELL—Yuba and Sutter counties.
D. W. KELLENER—San Mateo and Santa Clara counties.
C. E. WETMORE—Alameda county.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walls with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Portable Mulay Saw Mill,

With improvements recently made is unequaled as a neighborhood mill. It can be run by either steam or water power, and is especially adapted to the engines used for threshing.

It may be operated by either two or three men, and will cut as much lumber in proportion to the power and number of hands employed as mills of larger capacity.

It makes smooth and even lumber, leaves no stubshot, and will cut any sized log up to four feet in diameter.

It may be transported from one locality to another and re-erected ready for sawing in from two to three days, and can be made profitable in localities where there is not sufficient timber to justify the erection of a large mill. Send for descriptive circular, price, etc., to

CHANDLER & TAYLOR, Indianapolis, Indiana.

We also build the heavy Standard Circular Saw Mill, with either one or two saws as well as the Pony Circular Saw Mill that is capable of being run with light power. We also build Stationary Engines of varied capacity; also, portable Threshing Engines.

Pacific Iron Works.

Established in 1850.
RANKIN, BRAYTON & CO.
Office—127 First Street, San Francisco, Cal.
Builders of Engines, Boilers, all Classes of Machinery.
PLANTS FOR GOLD AND SILVER MILLS,
Embracing the latest and most Improved Machinery and Processes for Base and Free Ores.
WATER JACKET SMELTING FURNACES,
For both Galena and Copper Ores of the Most Improved Construction.
Having Built nearly every successful working Furnace on the Coast, we are prepared to guarantee the best results attainable in all classes of Ores.
HOISTING AND PUMPING MACHINERY,
Embracing all Known Improvements.
WHEELOCK'S AUTOMATIC CUT-OFF ENGINE,
Beyond Question the most economical and perfect working Engine now made.
WALKER'S COMPOUND STEAM PUMPS,
The best in use. W work with thirty per cent. less steam than any other Pump in the market.
Sole Agents for HOWELL'S IMPROVED WHITE FURNACE.
The only successful Chloridizing Furnace made. Over fifty of them in use on this Coast.
Parties Wanting any kind of Mining Machinery are requested to send for Illustrated Circular.

William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL).
MACHINE WORKS,
210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.
Manufacturer of
IMPROVED PORTABLE HOISTING ENGINES,
FOR MINING AND OTHER PURPOSES.
Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.
Steam Engines and all Kinds of Mill and Mining Machinery.

L. C. MARSHUTZ. T. G. CANTRELL.

THE RISDON IRON AND Locomotive Works

Corner Beale and Howard Sts.,
SAN FRANCISCO, CAL.
W. H. TAYLOR, Pres't. JOSEPH MOORE, Sup't.

Builders of Steam Machinery
IN ALL ITS BRANCHES,
Steamboat, Steamship, Land
Engines and Boilers,
HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.
ORDINARY ENGINES compounded when advisable.
STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.
STEAM BOILERS. Particular attention given the quality of the material and workmanship, and none but first-class work produced.
SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.
WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.
HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.
SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.
PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

QUICKSILVER.

THE CELEBRATED A BRAND, SHIPPED
DIRECT FROM THE
NEW ALMADEN MINE,
For sale in any quantity by the producers. Car Load Lots will be shipped from San Jose for Nevada, Arizona and the East, or delivered at Pacific Mail Steamship Company's Wharf, San Francisco, without charge.

Good Land and Sure Crops.

There has been steady and tolerably rapid advancement made in the growth of a majority of the towns in Colusa, Butte, Tehama and Shasta counties. Especially is this so in the agricultural districts where the land produces at least fair crops in all seasons—wet or dry—as does the land on the Reading Ranch. Those looking for homes in California where diversified farming will pay every year; where wood and water are plenty and easy to be obtained, and other desirable advantages are to be had, should address the proprietor of the Reading Grant.

Some 14,000 out of 26,000 acres of the grant remain for sale at comparatively low rates, in quantities to suit purchasers, on easy terms. Prices range from $5 to $30 per acre. The tract is between two and three miles wide, with the Northern Division of the C. P. R. R. passing centrally through its entire length. Send postage stamp for free circulars containing information about Shasta County and these lands, to the proprietor of Reading Ranch.

VOLUME XLIII Number 19

Tustin's Ore Pulverizer.

It has been admitted hy many mining engineers that the rotary mill was snperior to the old system of stamp mills, if a snitahle machine could only be constructed for [securing all the advantages of the rotary principle; and nnmerons inventors have been endeavoring dnring the past few years to devise the hest adapted and most appropriate constrnction and arrangement for this pnrpose. In a measnre several of them have snccesded, bnt none of them have heen sufficiently perfect to take the plsce of the stamps nnder all circnmstances until the mill shown npon this page came to the front, and this, the inventors claim, will fnlfill all the conditions.

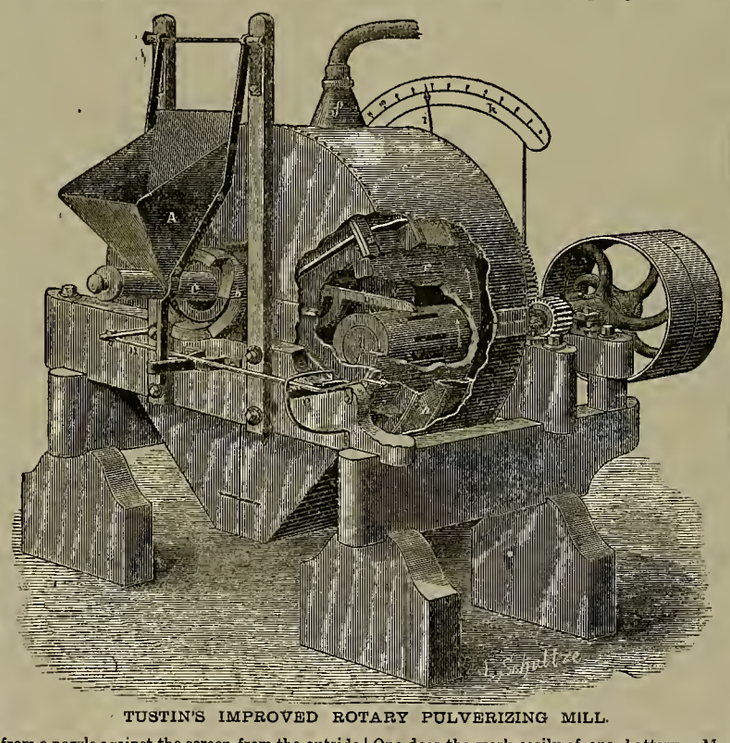
The Tnstin rotsry ore pnlverizing mill pulverizes ore wet or dry, and needs hnt a fraction of the power that the stamp mill requires. It feeds, crnshes, pnlverizes and screens the ore hy a continnons and speedy operation, and it has antomatic attachments wherehy the feed and working of its parts are regulated fully as systematically and positively as any other crnshing mill can he.

Like all other rotary pnlverizers it has a hollow cylinder or harrel which is mounted on hollow trnnnions and is driven hy gearing at one end of the machine. The harrel or cylinder, however, has a channel or trough extending aronnd it midway between its ends. The hottom or exterior of this trongh or channel is covered by a soreen of suitahle mesh. The interior of the harrel is covered hy a removable metallic lining which extends across the chanuel or trough and has transverse slots made throngh it directly opposite the trongh or channel. Inside of this harrel or cylinder the inventor places two or more iron cylinders or rollers, which extend across the bottom from side to side, and travel on the lining when the harrel revolves. It will therefore he seen that the ends of the rollers or cylinders rest and move npon the solid portion of the lining on each side of the slots. A flsnge or rim projects into the harrel aronnd the center opening in each head or end of the barrel, and the rollers rest npon the harrel helow these rims. A shaft passes across the center of the cylinder, on which is a loose head or sleeve. Two radial arms, marked *m* in the engraving, extend from the axial head or sleeve, one on each side of the series of rollers. This sleeve is connected with a pointer or indicator, *i*, on the ontside of the machine, and this pointer is arranged to move across an indicating scale, whioh is gradnated or divided into eqnal spaces. Now, when tho barrel is rotated, the friction will carry the rollers a short distance np the side of the cylinder, and the distance which they are carried np the side will he in proportion to the amount of ore contained in the harrel. As the rollers are carried up the side of the cylinder, they strike the radial swinging arm above them and move it np with them thus rotating the sleeve to which the arms are attached, and cansing the pointer to indicate on the scale the height to which the rollers are carried.

The greater the quantity of ore in the harrsl the greater will he the friction encountered hy the rollers, and the higher up the eide of the cylinder will they he carried, so that the pointer will always indicate how mnch ore the barrel contains. The channel or trough which snrronnds the rim of the harrel has partitions at intervals apart, and a wide slot or opening is made in the lining close to each partition. As fast ae the ore ie reduced to a oondition fine enongh to pass through the slots in the lining, it will fall throngh npon the screen, when the particles which have heen snfficiently reduced will pass through the screen. The large partioles will he caught by the partition, or rather shelf which extends across the channel and he carried up until the elevation causes it to drop through the wide opening or slot hack into the harrel again. The rollere are grooved or provided with pockets, which extend lengthwise of them so that, as they are caneed to rotate by the friction of the harrel traveling under them, the pockets will serve as huckets to catoh the ore which is ahove them and throw it over in front of them again.

The ore is fed into the harrel from a suspended hopper at one end of the machine, and is oondnoted by a spont or tnhe throngh the hollow trnnnion of the harrel. This hopper is snspended, and a ratchet device on the end of the rotating trnnnion keeps it agitated hy giving it snccessive knocks or concnssions hy which the ore is cansed to move forward throngh the tnhe into the harrel. The position of the hopper with reference to the ratchet device is adjnstahle, so that the force of the blow or concussion can he regnlated in order to increase or diminish the feed. To render the feed entirely automatic, the inventor has devised an ingenions device for connecting the swinging hopper with indicating pointer, so that when the pointer is moved over hy an excess of ore in the harrel, the hoppsr is moved outward, so as to lessen the feed.

In crnshing wet, a stream of water is directed



TUSTIN'S IMPROVED ROTARY PULVERIZING MILL.

from a nozzle against the screen, from the outside of the harrel. This hoth keeps the meshes of the screen clean and free, and supplies the water for reducing the ore to pulp, as a large proportion of the water which is directed against the screen will pass through the meshes of the screen into the harrel.

The construction and arrangement of the parts of the machine have heen decided npon with great care and attention, and the result is, that the machine has withstood as severe tests as it will ever meet with in practical work.

The rotary cylinder or harrel is enclosed in an outside shell or case, and it has a channel or hox entirely aronnd it, midway hetween its sides; *n* is the screen which covere the outside of the channel; slots or grooves marked *r*, allow the ore in the harrel to drop through onto the screen when it is reduced sufficiently fine; *d* are the grinding rollers, two or three of which can he used. The rollers have pockets made in them, which serve to throw the ore continually to the front; *f* is a water pipe through which water is delivered npon the screen, hoth to keep it clean and snpply water to the interior of the harrel. *A* is a suspended ore hopper, and *C*, the feed tnhe which passee through the hollow trnnnion and conducts the ore from the hopper into the harrel; *b* are inclined planee or teeth, which are carried by the rotary barrel and serve to jar the hopper and make it feed; *m* is one of two arms which are suspended on an independent shaft in the center of the bsrrel, one of which extends out on each side of the rollers, *d*; *i* is a pointer which is attaohed to the shaft that the arms, *m*, are secnred to; *k* is an indicating scale. This pointer indioates the quantity of ore in the harrel. The shaft to which the pointer is sttached is also connected with a system of levers, of which only one is shown, by which the feed is antomatically regnlated hy the same means that regulate the pointer.

This machine has heen [secnred hy letters patent of the United States. For further particulars address W. I. Tustin, No. 308 Mission street, San Francisco, Cal.

DODGE'S CONCENTRATORS.—Mr. M. B. Dodge has lately pnt two of his patent ore concentrators in Valentine's mill, Calaveras connty, where they are working well and giving satisfaction. One does the work easily of one battery. Mr. Dodge has just received a second order for these machines from the Rosario Mining Co., of Honduras. They have used the concentrators for six months, and having proved their efficiency, now send for more, Two were shipped, also, to Utah last week. At the lower end of the table of this machine ie a receptacle to receive auy fine mineral and quicksilver that might he left in tho gangue while passing over it, which can he removed from time to time, or discharged continuonsly. This ie one of the great advantagee claimed for this concentrator ahove all others. Slime mineral will not go against the current, hut will settle in the lower depression or well, and can he removed hy a shovel.

A CITY LEDGE.—The *Mountain Democrat*, El Dorado connty, saye: Wesley Keller is opening a quartz ledge on hie residence lot, Coloma etreet, thie city, from which he proposee to have a crushing of 20 tons made at the Brewster mill. He has already taken out 17 tons, a portion of which has heen delivered at the mill. He has made frequent prospecte, all of which have heen flattering.

NEGOTIATIONS for a commercial treaty between France and Italy will soon be satisfactorily concluded.

Water Jacket for Smelting Furnaces.

George W. Fogg, snperintendont of the Pacific Iron Works, of this oity, has just ohtained throngh the MINING AND SCIENTIFIC PRESS Patent Agenoy, a patent on a new form of water jacket for smelting furnaces. The improvements consist in a peculiar constrnction of a donhle inclosing wall forming the water space; and also in the employment within this water space of an intermediate cylindrical diaphragm, which is so snpported as to leave a space at top and hottom throngh which water may pass, so a circnlation may be kept np and the interior surfaces he kept cool.

Water is admitted into the space between the walls of the furnace, throngh pipes that may enter at any point, preferably near the hottom. The water is discharged throngh suitahle pipes, a current being kept np hy pump, pressure tank or other means.

In order to keep np a more perfect circulation and hring a cold body of water against the inner hot wall of the furnace, an iron cylindrical shell is formed of snch a size that it will he a vertical cylindrical partition between the outer and inner walls. This shell is made so as to leave a space above and helow, and is snitahly hraced, holted and supported.

Water heing forced in will flow to a point where it can pass helow the lower edge of the partition shell and thence np hetween it and the inner shell to the top. In its upward passage it flows also aronnd the tnyere-openings, and is also caused to spread around the inner cylinder. At the top it flows ontward throngh the upper passage, and the cooler water descends hetween the outer shell and intsrmediate shell to the hottom, and thence flows npward again in the narrow space hetween the intermediate shell and inner wall.

By this construction a strong onrrent of cold water is continnally forced against the inner wall of the furnace, and thns this wall is kept cool, and tho water is nsed with the greatest economy, heing forced in at all sides of the furnace. When it hecomes warm the heated portion will escape throngh the pipee at the top, the flow being snitahly controlled.

San Luis Obispo Mines.

During a recent trip down the ooast, the writer was shown, while at Cayucos, San Luis Obispo connty, some ores from the Polar Star mine, which is about 40 miles from Cayncos, and 14 from San Simeon. The ore contains about 2% to 2½% of quicksilver. Mr. David Lippman, of Cayuoos, informed ns that considerahle of this good rock is now being taken from the mines.

This mine was opened some years since, but was eventnally given up hy the company then at work, as it did not pay. Messrs. Whittaker and Slooum took hold of it afterwards and more thoroughly prospected it, working nnder a lease from the old company.

The ore comes from a tnnnel which was originally run by the company; but the tunnel at that time failed to find ore. The new parties, with more experience, hranched off from the main tunnel line a little, and struck this ore. They now have the old Bentley furnace at work on the ore from this tunnel. The old company spent eeveral thousand dollare on the mine, which they never got hack; hut the indicatione now are that the mine will pay. A few men are now at work and shortly some 15 men will he employed. The tnnnel hae been timhered and put in good shape, those having charge now heing practical miners. We have some specimene of the ore which were given to ns hy Mr. Lipoman.

THE Belcher folks will he the next to benefit hy the Sutro tunnel. It will be a great relief when they can hegin pnmping into the tnnnel. There will he a great difference between the expense of pumping 3,000 ft. and only 1,500. The tunnel ie fast approaching the point where connection with it will be made.

Custom Mill Wanted.

A correspondent of the Salt Lake *Tribune* writing from Marysvale, says:

The Copper Belt Mining Co. are rushing their 10-stamp silver mill to completion as fast as material and men can work.

The country generally shows a healthy and lively appearance. Men who own claims in the camp are filing in every day to do their annual assessment work.

We have not quite yet heard the whistle of the locomotive, but we know that the Denver & Rio Grande is coming. The line is established to this place, and is also extended to Panguitch, a distance of 60 miles south of here. Mr. Robinson is working a grading force in the canyon six miles below here, and another grading force is working in Clear Creek canyon, about 20 miles north of here. Altogether there is more life and animation around about this country generally than there has been for 10 years past. I don't know why it is, but it is a fact, nevertheless, that moneyed men lack confidence in this place or country. Perhaps it is because a few old scalpers, who dream of golden riches, have come to the country thinking to buy good prospects for about $2.50, that they know they can sell for a few thousand, and because they failed, have put Patrick's day over the eyes of all the prominent claims in the two districts; and then, again, we have a few old cranks who own some very good prospects, who are always on the sell, but when a genuine buyer comes along, they become suddenly wealthy and get very independent, and instead of selling for a good round sum, perhaps to a man who would do more in the camp in 30 days than they themselves would in 30 years, they want to hold or buy up the whole country, railroad included. Such are our drawbacks, and until parties come in the country who have sufficient nerve to go to work and put up a 10 or 20-stamp custom mill, the place will be a drag, for we have not enough high-grade ore that will bear shipping to keep the camp lively. The owners of most of the best claims are poor men, too poor to reduce their ores themselves, hence the necessity of a good square custom gold and silver mill. There is an abundance of ore in the two districts (Ohio and Mt. Baldy) to work within a few miles of a mill, but the owners of these claims can't go to work and pile the ore out on the dumps, for the reason that they are not able to get supplies, and unless they actually know that they can sell their ore when they do get it out, they must let it remain in the ledge.

The Sonora mine alone, would keep a 10-stamp mill running on $30 rock, then add to that the Great Western, the Bully Boy and Webster mines, the Fillmore and Occident, besides a dozen undeveloped claims with plenty of milling ore on the surface, what risk would there be in building a 10 or 20-stamp mill? It ought to be a good investment. The fact of a few men incorporating and selling the stock of some ground on Ten Mile creek should not discourage men from investing a few dollars in Bullion and Cottonwood canyons, where so much reality exists, and is actually in sight.

Two Ways of Skinning a Cat.—A correspondent of the New York *Mining Record* says the difference between the California and Colorado methods is about as follows: They both will result in the same end. The Californian will buy a mine with his own money, thoroughly equip it with good machinery, work it systematically, pay dividends for awhile if he has the ore, and if he has not he will buy it to pay dividends with. He soon runs the stock up to a good figure and then unloads. He will, in order to sell his stock, sacrifice his wife's relations—even to his mother-in-law. When he wants the stock back he will assess it till he freezes his friends out, and then play the old game again. Now we of Colorado do a little differently. We find a mine or claim, and instead of doing like the ignorant Californian (put our own money in), we get our wives' relations to put up. We then spend from $1,000 to $2,000 for a five-horse-power engine to put on the claim. We employ a general or a professor (by brevet) who has had generally six months' experience, and put him in charge to develop the mine. In a short time he has the mine in a good condition. His underground work resembles the wanderings of a blind gopher in a clover patch. We then subsidize one or two papers to puff the general, not the mine, so we can sacrifice our relations by selling stock that is not likely to pay dividends for the next century. Our ways differ slightly, but end in disgusting those who would otherwise invest in mines.

Reduction Works of Arizona—Locality and Capacity.—Arizona has 55 stamp mills of from 4 to 80 stamps each, aggregating 585 stamps. Of the entire number only one mill is run by water power. Cochise county has 9 mills, aggregating 115 stamps; Gila county, 12 mills, 79 stamps; Maricopa county, 3 mills, 95 stamps; Mohave county, 7 mills, 60 stamps; Pima county, 5 mills, 52 stamps; Pinal county, 4 mills, 37 stamps; Yavapia county, 15 mills, 127 stamps. The Vulture, Maricopa county, heads the list with 80 stamps.

Quick Cement for Glass.—The *Polytech. Notizblatt* gives the following receipt for glass cement: One part liquefied amber and 1½ parts sulphide of carbon. Apply this to the broken edges of the glass with a brush; press, and it will dry at once.

Bad for Copper Interests of Globe.

The following items about the shutting down of the Carrie company's smelting furnaces we take from the Arizona *Silver Belt:*

The Carrie company's smelter was shut down on the 20th inst. Mrs. Geo. Scott had put an attachment on the property a few days before, which was removed by the payment of her claim. In the last difficulty, the Tucson firm of L. Zeckendorf & Co. are the movers. Their claim is for some $21,000. The 74,000 lbs. of copper shipped last week went to their house, and the company are not credited with it in the account rendered. When the settlement occurs this will no doubt be done; and as the copper is probably worth 10 cents a lb., it reduces the indebtedness to $13,600. There are about five tons of copper since shipped, which reduces it still more. We understand that all local indebtedness has been paid; if so, the whole claim against the property cannot be more than $12,500. To offset that debt there is an excellent plant, a good mill site, three mines (the Carrie, the True Blue and an extension of the Orion), the first two of which have been producing the ore upon which the smelter was running. We have been informed that the condition of the True Blue is particularly good at present, as there is considerable ore in sight, and easily got at. There is no reason why this property should be idle, and we are satisfied it will not be long. We cannot blame Zeckendorf & Co.—they have a right to secure themselves; but we regret the occurrence, as it may operate adversely to the copper interests of Globe.

The Carrie copper company's non-success is simply another illustration of what we have so often condemned—the folly of sending men to run a business who are not experienced. Those Eastern men would not send a banker's clerk to plaster a house, but they acted just as foolishly in sending untrained men to run mines, or smelters or mills. The experience they acquire costs them dearly, but they do not profit by it.

Cochise District.

The Tombstone *Epitaph* says: From a gentleman who recently visited this section we learn the following: The Russell Gold & Silver Mining Co. own the Peabody, Copper King, Highland Mary, Donna Anna and Tam O'Shanter, the first two of which have received considerable development—but mainly the Peabody. While this can hardly be called a mine as yet, it is a most flattering prospect, and there is little room for doubt that the company will be able to keep their 30-ton smelter in constant operation when it shall have been set up. Besides a few shallow prospect shafts, all showing fine copper ore, there is an incline shaft of 97 ft, having an actual depth from surfaces of about 70 ft. Thirty ft down the shaft an elbow drift of 57 ft has been run in copper ore. This connects with an air shaft. At the bottom of the shaft a 30-ft drift has been run on the ledge which shows 6 ft. wide. There are about 400 tons of ore on the dump, that from samples run 36% copper and 26 ounces of silver to the ton, though a great deal is of high-grade, both in copper and silver. On the 17th, water was struck in a well at Cottonwood, three miles from the Peabody mine, in sufficient quantity to guarantee the erection of the smelter at that point. The smelter is from Rankin, Brayton & Co. (Pacific Iron Works), is of 30-ton capacity and is now at Summit station. It is expected to be in position in from five to six weeks. Four miles to the northwest a rich strike has been made in the Accident prospect, showing a good deal of high-grade petanka. This spur of the Dragoons is alive with black and white-tailed deer and bear.

Nitre.—It is reported that considerable beds of what is supposed to be saltpetre have been found near some small lakes in the neighborhood of Ragtown, seven miles below Fort Churchill. For many years these lakes have been famous for their deposits of soda, which mineral is there dug up in great purity, large cakes of it resembling ice. At one time parties in this city bored a well in the solid rock near one of these lakes to the depth of about 150 ft. in search of petroleum. After boring to this depth at considerable expense it was thought that it would be well to make a critical examination of the indications. What first induced the company to begin boring was a scum of an oily substance found floating on the water at the edge of the lake. A new examination was made, and it was found that the oily matter was merely a substance exuded by a sort of worm or grub living in the waters of the lake. So says the Virginia *Enterprise.*

The Atrato Mining Co., formed to pump up golden mud from the bottom of certain rivers in Central America, have let go to take a better hold. They have stored their mud-pumping machinery, and now announce that they will hereafter be a hydraulic and quartz mining company. Several "golden mud" pumping companies now being formed in the East can take warning by this company's experience, which ignored the experience in the same line already gone through in California. Pumping up gold from the bottom of rivers can be done well on paper, but not in any other way.

Important Ruling on Conflicting Claims.

The following letter explains itself:

General Land Office,
Washington, D. C., Oct. 8, 1881.

Register and Receiver, Salt Lake City, Utah:

Gentlemen: On the 7th of May last, the Rebellion Mining Co. presented at your office two applications for patent, one being from the Rebellion lode, designated as lot No. 193, and the other for the Mulcahy lode, lot No. 194, which applications were rejected by the Register, for the reason that a portion of the land embraced in each application conflicts with claims previously applied for, to wit: The Rebellion Lode conflicts with the Bibleback, lot 177, the Samuel, lot 178, and the Fallon, lot 179; while the Mulcahy conflicts with the Samuel and Fallon claims, for all of which applications for patent are now pending in your office, and to which the Rebellion Mining Co. duly filed adverse claims for the area in conflict, thereafter in due time instituting suits in court to determine the right of possession.

From the Register's action in rejecting the Rebellion company's applications, an appeal has been taken to this office. Inasmuch as the decision is in accordance with the previous rulings of this office (Huggins vs. Chavanne) and a correct construction of the law, no error was committed.

In the case cited it was held that "the rule which forbids the reception of an application for patent to a mining claim which conflicts with a claim embraced in a prior pending application is derived from that provision of the statute which prescribes the mode of filing adverse claims. Where the statute prescribes one way no thing shall be done it precludes every other. Chavanne having made application for patent to the Elk mining claim, Huggins as owner of a conflicting claim, had but one method open to him to protect his interest and have his right determined."

It is easy, it would seem, to see that this rule is a salutary one, for were it otherwise application after application might be accumulated in the local offices all relating to the same land, thus nullifying the law which requires adverse claims to be filed and prosecuted.

From the argument of counsel I understand that the Rebellion company simply desires these proceedings for patent to progress so far that it may, in the event of judgment in its favor by the courts in the controversies pending against the Bibleback, Samuel and Fallon, claimants, enter its claims entire.

The proper method to accomplish this end is by excluding from its applications the area in conflict with the claims previously applied for, as shown by the accompanying claims.

It is urged, however, that should this be done, it would amount to an abandonment of all the ground in conflict. This is clearly a mistaken conclusion. Such an exclusion is not relinquishment. The company's right to the land in conflict has been asserted by the filing of adverse claims, which relate only to the land in conflict, and this was the only way by which it could assert title to such portions of its claims. The proposed applications will amount to an assertion of the right to the remaining portions. Now the plats of surveys and field notes properly describe and show the entire claims, also correctly representing the areas of conflict. It would be a somewhat difficult matter to prepare for publication and posting, notices which shall describe only those portions of the claims not in conflict, than requiring no words of exclusion, without having prepared amended surveys. In order to avoid the trouble and expense incident to such amendment it is regarded sufficient for executive purposes if words of exclusion be used in the application and notices which effect only the present proceeding; but patents could not issue for the portions so applied for separately from the portions in controversy without amended surveys.

The company must amend its applications so as to exclude the conflicting areas therefrom, which exclusion must also be recited in the published and posted notices, and I see no objection to adding thereto one express declaration that it thereby relinquishes no right or title to the areas so excluded, although I deem such declaration wholly unnecessary.

Should it appear, upon proper proceedings being had, that the company is entitled to the land as applied for, and the courts adjudge it to be the amount of the areas in conflict, it may make entry of each lot as if applied for entry.

Very Respectfully, N. C. McFarland,
Commissioner.

Large Cast Iron Wheels.—Three fly-wheels have been lately cast at Mr. Lycett's foundry, Wolverhampton, Eng., each wheel weighing 40 tons in the rim, and cast in one piece. The diameter is 26 ft.; depth, 23 inches, and measure across the face, 15 inches. Each rim will have eight arms affixed, which will weigh about 25 tons, making the total weight of each wheel 65 tons. Fly-wheels weighing 65 tons have been cast in that district before, and some of them with a diameter of 30 ft., but it is believed that they have all been cast in either two or more segments.

A Prediction Verified.—Several years ago Ericsson predicted that the Nile and the Gangee would be lined with cotton and other factories driven by solar heat. A French engineer in Algiers is already contributing to the fulfillment of this prediction by pumping water and making it boil by solar force alone.

How to be Dismissed.

R. R. Bigelow, of Elko, Nev., writes to the General Land Office that some years ago the owners of a certain mining claim procured a survey thereof and filed an application for patent, but proceeded no further than publication of notice; that since that time the claim has been relocated as abandoned property, and that the present owner is desirious of obtaining a patent, but no survey thereof can be had, as the application of the former owners is still upon the records of the local land office, and he now seeks to learn as to the manner in which a dismissal of the application can be secured in order that a new survey may be made upon which to base an application for patent by the present owners. The Commissioner replies "that a party desiring to file an application under the circumstances stated should transmit to this office his affidavit, and that of one or more disinterested persons, reciting the facts in the case, giving the date of the original location, the time when work upon the claim was suspended by the former owners, date of relocation by the present owners, and such other material facts as will establish a *prima facie* case of abandonment.

If such a case be established by said affidavit, the register and receiver of the proper land office will be instructed to order a hearing in the matter, giving notice to all parties concerned; and if the result of such hearing be to sustain the allegations of the claimant, the application of the former claimant will be dismissed and the premises restored to the public domain, subject to entry and patent by the relocator upon complying with the provisions of law.

New Smelter.—The following item about a furnace in Globe district, Arizona, we take from the *Silver Belt:* "Gen. MacDonell, of the Buffalo mining company, has a large force of men employed, and would soon be in a position to ship copper if he could get his machinery in. The form of smelter he has erected looks somewhat primitive beside the more pretentious water jacket, but it is said to be very effective. It is simply a large perpendicular square flue, built of well-dressed stone, and 30 ft. high. Five ft. from the top the feed opening is placed, and from there to the bed of the furnace it is 15 ft. It has a capacity of 15 tons daily. It has stout copper plates set in the masonry where the heat will be most intense. It will be firmly secured from damage from expansion by stout iron clamps. The slag and metal discharge openings will be in the front. The low position of the smelter gives little show for a slag dump, but that will be obviated by the erection of a derrick with a 30-ft. arm, which will lift the slag pots and swing them 60 ft. from the furnace. The cost of the furnace will not exceed $700. This is the same form of smelter that is used at Clifton, A. T. A smaller one, of the same pattern, was used by Ignacio Campbell at the Wheatfields with success."

Strontium.—On a late visit to Mazourka canyon, Mr. Woodhull, of the assay office, found a mineral that on investigation proved to be a sulphate of strontium. It is of a bluish white color and looks much like marble, but has a much higher specific gravity. In mineralogy the mineral is called celestite. The metal, strontium, is of a pale yellow color, and is but little used in the arts. The nitrate of strontium is used in the manufacture of fireworks, and it imparts to flame a beautiful crimson color. A process recently introduced in German beet-sugar manufactories, has created a demand for strontianite, and it is reported that mining for it is going on quite extensively in Westphalia, Germany, notably at Dasheck and Denstreinfort, near Munster. About 4,000 to 5,000 cwts. are now gathered, and there has been some excitement among peasants, who, ignorant of the value of the mineral, were led into unfavorable concessions of mineral rights by outside speculators. Possibly it might prove worth the while of some of the prospectors in this country to inquire into the possibility of supplying the German markets.—*Inyo Independent.*

Sawtooth Mines.—In our last we omitted to name one peculiarity of this great mine, the Pilgrim. It has a clay or putty-like seam running near the center of the vein from the inner end of the tunnel for hundreds of feet toward the mouth. In the foot wall half of the lode, the rock is hard; and the other half the entire space seems to be filled with decomposed ore. We never saw any other mine with these characteristics, and yet, it seems to be elementary with this one, rising above and continuing below the tunnel, which is a large, fine one, being cut sufficiently spacious and well constructed for working the mine to advantage.—*Challis Messenger.*

A Good deal of prospecting is still being done at the old Meadow Lake diggings, and it is now reported that a ledge containing rich ore, that is free milling, has been found. Most of the ledges were free milling at and near the surface, as many old Comstockers remember to their sorrow.

The Savage company are now taking out about 50 tons of ore per day from the Sutro tunnel and Potosi tunnel levels. They are drifting in on the 1100 level, and will shortly begin prospecting a block of virgin ground reaching from that point up to the 400 (or Potosi tunnel) level.

MECHANICAL PROGRESS.

Tests of Constructive Material.

One of the most interesting exhibits, both to the engineer and mechanic, as well as to the general visitor, at the fair of the Massachusetts Charitable Mechanic Association now in progress at Boston, is that sent from the Watertown Arsenal. The exhibit consists of materials which illustrate the results of tests made by engineers in the service of the government upon a machine specially constructed for the purpose. The arrangement of the exhibit is such that each article tells its own story, while those persons who are sufficiently interested to desire the particulars may learn them from a pamphlet near at hand. The exhibit consists of three groups of objects, which have been ruined respectively by tensile strains, bursting strains and compression.

One of the objects most likely to attract popular attention is a steel-wire cable of the kind being employed in the East River bridge. The diameter of this cable is 1¾ in., and the strain to which it was submitted was 150,000 lbs., or 75 tons. The cable itself remained intact with this severe test, but the bail of the socket parted, which shows, like many others of the Watertown experiments, that in constructions of this class the weakest point frequently lies, not in the cable itself, but in its fastenings or fittings.

A hammered-iron bar 5 in. in diameter was broken by a tensile strain of nearly 723,000 lbs., or 36,900 lbs. per sq. in. Under this tension the bar parted *with a loud report*. The fracture shows a crystalline structure. A smaller wrought-iron bar was broken asunder by a tensile force of 51,340 lbs. per sq. in. This bar drew down at the place of fracture, and shows a fibrous structure at the break.

In the group which contains specimens destroyed by compression, two iron columns of different forms give some idea of the relative value of the shapes shown in supporting great weights. A latticed iron column some 10 ft. long, of a pattern quite familiar to all who are acquainted with bridge work, was ruined by a pressure of 574,500 lbs. A circular flanged column, known as the "Phœnix" pattern, and of much smaller size and weight, sustained nearly 50,000 lbs. more than the weight above given. Tests of this kind have determined definitely the value of the latter form, but its liability to deterioration from oxidation upon the inside detracts somewhat from its value in practical use. An 8-inch column of the "Phœnix" pattern which had been subjected to a test for compression, shows, by the perfect symmetry of its present crushed form, how perfectly it is adapted for supporting weights.

A much-needed lesson to builders is splendidly illustrated by pine columns, which have in some instances supported remarkable pressure. The first of these columns, originally 12 ft. long, yielded to a pressure of 190,000 lbs., the weak spot being a large knot which acted as a wedge and caused the destruction at less than the proper figures. Another of these columns is a stick 12 ft. in length, tapering from about 7¾ in. to nearly 6¼ in. in diameter. This stick, being practically perfect, has shown its weakest point to be at the smaller end, for it is at that point that the crumbling of the fibres has taken place. As an argument against the prevalent custom of turning down wooden columns at the end this test stands unquestioned.

A seasoned herd-pine girder 11 in. square and 10 ft. long, when tested, bore the astonishing load of 751,000 lbs.—a conclusive proof of the value of such timber for columns.

As an example of bursting strain, a model one-third size of the breech of a 10-inch cannon is shown in the center of the section. This cannon was partly filled with beeswax, and a close-fitting steel plug was forced into the aperture. Under a pressure of 599,000 lbs. the model, being a stout casting 2 ft. long by 11 in. outside diameter, was fractured in every direction.

Several other interesting tests of steel bars, cast bars, boiler plates, etc., complete this display. It is a graphic method of showing facts that are of interest to every thinking man. It is a popular presentment of facts frequently published in technical journals, but not easily accessible to the average reader.

IRON AND STEEL ROLLING.—An interesting experiment was recently made at a rolling mill in Germany, to ascertain the relative proportions of power required to roll an ingot of iron and an ingot of steel, each of similar weight. The pile of iron was passed through the rolls under a steam pressure of 57 lbs., and was brought to its desired form, without any material diminution of speed, so that the rolls were at once ready to receive the next charge. The steam pressure was then allowed to increase from 57 lbs. to 71 lbs., and the initial velocity was also materially increased at the moment of placing the steel ingot in the rolls. After the steel ingot had been brought to the same form as the previous one of iron, the speed and pressure was so much reduced that had another ingot been put in at once, it would have stuck fast before the rolling could have been half completed. It required 40 revolutions of the engine to recover its initial speed. The increase of power for manipulating steel over that required for iron, is therefore very considerable—much more than is generally supposed.

HEATING METALLURGICAL FURNACES WITH COAL DUST.—An improved apparatus by which coal dust and other pulverized fuel can be efficiently and economically utilized for the heating of metallurgical and certain other furnaces, has been invented by Mr. G. M. Thompson, of Paris. The apparatus in question is composed of a hopper, through which the pulverized fuel falls upon a horizontal shaft provided with worms or screw blades working in opposite directions from the center, the said shaft being operated by any convenient motor. By these worms the fuel is carried into funnels beneath each end of the hopper, whence it falls into air pipes, in which, after being thoroughly mixed with atmospheric air, it is blown into a combustion chamber, where it is instantaneously ignited and entirely consumed. The amount of air required to effect perfect combustion is regulated by suitable registers, and the admission of the fuel is controlled by a pulley set on the worm shaft; the uniformity of the feed being secured by agitators set upon a longitudinal shaft, which, passing through the hopper from end to end, is rotated by suitable gearing. The form, dimensions and general details of construction of the apparatus may be varied according to its intended application.

LAGGING FOR STEAM PIPES.—A French mechanic of some experience, says a contemporary, recommends the following process for producing a lagging for steam pipes, which, besides being comparatively inexpensive, appears to be very effective: A long tube of some flexible material, such as canvas, is drawn over a metallic pipe of approximately the same diameter. Either of the ends of the canvas tube is bent over, so as to reach into the interior of the metal pipe, and is pulled through it, while at the same time quantities of cloth fibers are introduced, so as to completely fill it. After one length of the canvas tubing has been partly disposed of in this manner, another length may be drawn over the metal pipe, as before, one of its ends being connected with the piece almost drawn through. Having done this, the additional length may be drawn through, this process being carried on until a sufficient length of lagging has been obtained. Its cross section is round, as a matter of course, and may be altered by subjecting the lagging to the process of rolling.

HAULING FIRES.—When a boiler is short of water and a heavy fire is on the grate, what shall be done to prevent the boiler from being burned? The first impulse is, on the part of some, to haul the fire at once, but is not that the most dangerous course that could be taken? It seems open to criticism. A fire that is disturbed, is intensely hot for a short time, at a period when no more heat is needed, and it would therefore seem that it would be better to open the doors and throw wet ashes on to smother the fire, instead of adding to the danger by raking it over. By so doing, the heat is at once lessened—at no time increased—and the pressure is falling, but when we haul a fire, the exact reverse occurs, more steam is made and the danger increased. We think it is safer to cover the fires than to haul them, particularly if they are of bituminous coal.—*Mechanical Engineer.*

COMPOUND STEAM ENGINES.—Hallauer's recent experiments have led him to the conclusion that the difference between engines of one and two cylinders, in point of economy, is very slight. In ranging from 80 to 8,000 horse power, with revolutions varying from 25 to 90 per minute, the expenditure of steam for a given amount of work remains the same for the same type of motor; the consumption for two cylinder motors are identical for Woolf and compound, whatever may be the volumes of the cylinders, provided the motors are regulated so as to give the maximum efficiency; the expenditures of steam in motors of one, two and three cylinders, suitably regulated and constructed, are so nearly alike that the choice may be governed in each instance merely by the fitness of the type of the engine for the particular purpose desired.

CONNECTING WIRES.—Mr. Thomas Ellis, of Coatbridge, Scotland, proposes a new method of connecting metallic wires, the manner of proceeding being as follows: A piece of iron, similar in shape to an olive, is pierced at the ends to admit the insertion of the wires, two larger holes being situated near the middle, through which a pair of pincers may be passed to head back the extremities of the wires in such a way as to form a sort of ring. This fastening is, moreover, easily undone when required. Instead of bending the wire, a small nut may be applied to its extremity, or what is better still, the olive-shaped iron may be tapped in order to fasten the wire. The mode of connection is especially convenient for telegraph wires.

MOLDS FOR CASTING STEEL UNDER PRESSURE. Mr. C. J. Allport, of London, proposes to use asbestos for making the joints of molds for casting steel and other metals under pressure. The method of accomplishing it is to either use strips or rings of asbestos, millboard, or asbestos fiber made into a gasket between the bottom of the ingot mold and the bottom upon which it stands, and the lid and the top of the mold, and if the mold is made into more than one piece, between the joints of the different pieces.

GAS ENGINES.—The Otto gas engines on exhibition at the electrical exposition in Paris, vary in power from half-a-horse to 50-horse.

SCIENTIFIC PROGRESS.

The Moon and the Weather.

M. De Parville has published in the *Journal des Debats*, a paper on the temperature of the present year, which, at Paris, has risen to a height exceeding all previous authentic records. In the course of the article he raises the question as to whether the dryness of the present summer could have been foreseen, and answers it in the affirmative. Having then referred to the influence of solar action on the atmosphere, he says: "A very long series of observations has also shown that the moon, which passes every month from one hemisphere to the other, influences the direction of the great atmospheric currents. The changes in those currents, in consequence of the prevailing moisture or dryness, are intimately connected with the relative position for the time being of the sun and moon.

The distance of the moon from the equator, that is, the inclination of the moon's path to the plane of the equator—varies every year, passing from a maximum to a minimum limit; and the meteorological character of a series of years appears to be mainly dependent upon the change of inclination when these extreme limits have been touched. Observations prove that the rainy years, the cold winters and hot summers return periodically, and coincide with certain declinations of the moon. In our latitudes the rainy years occur when the moon's declination has touched its extreme limits of 28°, 26° or 18° respectively. They are separated from each other usually by periods of about three years, and then six years." M. de Parville then gives a list of rainy years running back to 1783, the most recent being 1879, 1876, 1866, 1859, 1856 and 1853, in each of which the moon's declination was either 28°, 26° or 18°, beginning with 26° in 1879 and running back in the order named. The severe winters, he says, coincide as a rule within a year of the same declinations. The dry summers come naturally in the middle of the period which divides two wet years. The next wet year ought to coincide with the declination of 18°, therefore, with the year 1884, as the last was 1879 with the declination of 26°. Between the two years comes the period of maximum dryness, and it may be expected, therefore, that the year 1882 will be another dry year.

The Influence of Telegraph Wires on Lightning.

Some interesting facts in the above connection have recently been brought out by M. Montigny through observations along a railroad telegraph line in Belgium. It appears that the wire for a considerable distance passes along extensive lines of poplar trees, while the road rises gradually from a plain to an elevation of about 200 ft. A close examination shows that along this route only about 1% of the trees have been struck by lightning on the plain, and on the slope about 25%, while upon the highest portion of the line not less than 64% of the trees show evident marks of injury from lightning.

M. Montigny distinguishes three kinds of injuries: First, the bark torn and detached on a limited part of the trunk; second, a furrow, straight or (rarely) spiral, made on the tree, from near the wire, down to the ground; third, a peculiar oval wound, with longer axis vertical and lips colored light brown. The furrows, which are probably due to the most violent discharges, are relatively most frequent on the upper and western slope, which the storms usually reach first. M. Montigny is of the opinion that the lightning, while provoked by the wire, does not strike that first and then the tree, but strikes the tree directly.

His conception of the process is to the following effect: Suppose a thunder cloud charged with positive electricity. A long telegraph wire under it, though insulated, may acquire as great negative tension in the nearest part as if in direct communication with the ground; and the tension is greater the nearer to the cloud. While the inductive influence affects the wire most, objects that are near, such as trees, share in the influence according to their conducting power. The lightning is attracted in the direction of the wire, yet does not strike it; the insulating caps present an obstacle to its prompt and rapid escape to the ground. It finds a better conductor in a neighboring tree wet with rain.

LIVING ANIMALS LIT UP FROM WITHIN.—At a recent soiree in the Paris Observatory, M. Trouve showed a live fish with its body lit up from within by his electric polyscope, a minute form of which, with conducting wires passing to the hands of the operator, the animal had been caused to swallow (comfortably, let us hope). The whole body became transparent in the dark, so that the vertebræ could be counted and all the details examined. This instrument promises to have many uses. Among others, it has already been applied, *La Nature* says, to showing students the texture of the rectum and bladder, to facilitate extraction of a projectile at the back of the nose, to examine the stomach of a bull (in which a gastric fistula was formed), to lighting the interior of shells and cannon for examination, also to lighting powder magazines, in which case the reflector is inclosed in a triple envelope of glass.

METEORIC ORGANISMS.—At the late meeting of the British Association for the Advancement of Science, held at York, during a discussion as to the lately mooted question of the discovery of vegetable fossils in a meteoric stone, Sir William Thomson observed that in all probability some of the vegetation existing was of meteoric ancestry. The stone in question was not on the earth a quarter of an hour before it was picked up, and it was certain that it came from outside the earth. He also said there was a general consensus of sentimental belief that in many other bodies in the universe there was something like the life on this earth, but that was not a scientific belief; however, science was in what might be called a skeptical condition. Life elsewhere was a possibility, and science only went the length of saying that life elsewhere was not impossible. At the same time he did not say that the sentimental belief might not be as well founded as any scientific belief, but all he could say at present was that such a belief was not founded on scientific grounds.

SCULPTURING WITH STONE IMPLEMENTS.—It has been held by some archæologists that the ancient sculpturings could not have been cut without the use of iron tools; but others have of late years succeeded in reproducing similar markings on granite slabs, using solely stone implements; and in doing so they found that diorite and other such tough stones cut the granite better than flint. This corresponds with the practice of the stonecutters of the present time, whose steel tools for cutting granite are of a much softer temper than those they use for sandstone. The great sculptured stone of Montezuma, in Mexico, is a striking proof of the extent to which granite can be sculptured with stone implements. Gama, in his work describing this stone, states that 10,000 Indians were employed in transporting it to the City of Mexico, where it was sculptured by 30 workmen with stone axes.

MAGNETIC PROPERTIES OF NICKEL AND COBALT.—M. A. Gaiffe, says the *Electrician*, has made some fresh experiments on the magnetic properties of nickel and cobalt, the specimens being obtained by an electro-chemical process, the currents employed being of sufficient intensity to render the metals very hard. Having divided them into bars of nearly equal dimensions, some of them were left in the hard state, others were annealed, and others again were annealed and forged. All of them were magnetized at the same time and in the same way, and measured by means of a magnetometer. After being left for 36 and 72 hours, they were again measured. He found that their magnetic properties increase, and concludes that this is owing to the presence, when first taken out of the bath, of hydrogen in combination with the metal, which paralyzes the magnetic power.

LUMINOUS METEORS.—At the recent session of the British Association, at York, Prof. A. S. Herschel read the report of the committee on luminous meteors, in the course of which he referred to the aerolite which fell near Middlesborough this year, and embedded itself to a considerable depth in the earth. It was estimated that it struck the earth with a velocity of 402 ft. per second. There was no doubt it fell at least 40 miles. Sir William Thomson said the great majority of meteoric stones, instead of falling to the earth in a solid mass like the one produced, generally got shivered to pieces in the air through becoming so intensely hot. Prof. Herschel observed that the stone in question had not been exposed to any great heat

NEW MODE OF TELEGRAPHING.—*Nature* reports that a telegraphing experiment of a singular description was tried about the middle of August at the Trocadero. It consists merely in the reading of large silvered zinc letters, a square meter in size, fixed on a blackened board, by refracting telescopes. This method has succeeded very well from the Trocadero to the Pantheon—a distance of three miles. The inventor, an officer in the French service, thinks he will succeed in reading messages at a distance of 60 miles under favorable circumstances.

A NEW METAL.—A vein of what is supposed to be a new metal, is said to have been found in digging a well near Battle creek, Mich. The find is in a stratum of rock about 28 ft. below the surface. Pieces of some of the nuggets taken out, it is said, have been melted up, and have all the appearance of the best gold, but when the acid test is applied to the metal it corrodes, showing that it is not the genuine precious metal. It is not known what metal it is, and specimens have been sent away for analysis.

A NEW USE FOR ELECTRICITY.—Electricity is now employed in the rectification of inferior alcohol. This work is accomplished by passing a current, generated by a voltaic battery and a dynamo-electric machine, through it. By this operation the superfluous hydrogen is disengaged, and beet-root alcohol, which is usually very poor, can be made to yield 80% of spirits, equal to that obtained from the best malt.

LONG TELEPHONE CIRCUIT.—The telephone has been successfully worked over a distance of 350 miles between Buffalo and Pattersoa in New York and New Jersey States. The voice could be recognized, but owing to the sputtering and snapping caused by induction (the wires were close to the ordinary lines), the words could not be distinguished.

so universally confident of a brilliant and permanently prosperous future.

INYO.

No Sale as Yet.—Inyo *Independent*, Oct. 29: Notwithstanding the efforts of several mining men representing capital, there is no sale of the Keynot gold mine to be reported yet. Word comes pretty straight that Peter Taylor, backed by a San Francisco company, will soon be on hand with plenty of cash capital to capture the whole works. Uncle Peter is entitled to immense credit, for having practically brought out the district, and we sincerely hope he and his company will get the mines.

Virginia Con.—Mr. Chenot, superintendent of the Virginia Con. mines, on Kearsarge peak, has just put on a small working force of miners. We understand that operations will be confined to searching out and opening outcroppings on the line of the Virginia ledge, which is judged by those best informed to be one of the very best on the mountain. Some very rich gold and silver ores from the mines were worked at the Pioneer mills in early days.

Poleta.—We hear that several miners have been discharged, owing to the impossibility of working advantageously to any greater depth without hoisting machinery. It is said that works are to be put on the mine right away.

Panamint.—Supt. Pheby arrived at Darwin last Saturday, en route to Panamint. It is said that he will immediately put on a large force, in mining and rebuilding the road.

Keyot Bullion.—As near as can be learned, some $13,000 in gold has been shipped to Lone Pine from the Taylor mill during the month.

MONO.

Bodie.—*Free Press*, Nov. 1: Probably all the mines now running will be kept in operation during the coming winter, and not impossibly others may, after the deep shafts have drained down somewhat deeper, take up their work where it was left off months ago in consequence of too much water. The Standard shaft is now down 1,090 ft, the Lent 775, and the Red Cloud 640. The Lent reports most of its water from the 700 and 740 levels, and not from the bottom. The Red Cloud has far less to contend with in this regard than formerly, and there seems a reasonable probability that as still greater depth is attained, the obstacles which this element has presented may disappear altogether. The completion of the Mono Lake railroad will render it possible to obtain supplies of wood and lumber in the winter time without greatly increased cost or inconvenience. The Standard-Bulwer mill has been undergoing a thorough overhauling the past week, the first for a year and a half. The Noonday mill, of 40 stamps, has completed its contract with the Bechtel, and has resumed crushing ore from the Noonday and North Noonday mines. The contract of the Oro Co. with the Silver Hill has also expired. The Tioga, Blackhawk, Champion, Goodshaw, Addenda, and others of our mines, are prosecuting their explorations steadily. The Bodie Tunnel mill it is anticipated will be completed by the 1st of December.

Bodie Con.—There were 122,465 tons of ore hauled to the mill during the week ending October 29th, and 117,472 tons were crushed, yielding $9,977.95, or an average yield of $50.40 per ton. The average assay value of the pulp was $64.43 per ton; that of the tailings $11.52, so that the average value of the ore worked was $70.02 per ton. The amount of ore extracted during the week was 100,402 tons, as follows: 43,812 tons from the 5th level stopes, and 56,590 tons from the 0th level stopes and winzes.

Standard Con.—During the week ending October 29th there were shipped to the mills 495 tons of ore from the 300, 385, 500 and 550 levels. Average pulp assay for the week was $60.60; crude bullion received, 4,000 ozs, and the amount shipped to the company, $21,207.79. The shaft is down 1,090 ft.

Bodie Tunnel.—There has been a decided improvement in the mine during the past week, the ore in the upraise of No. 7 being of a high grade, 2 ft wide. Ledge No. 20 in the stopes north shows 5 ft of ore between the walls.

NEVADA.

The Peabody Mine.—Footbill *Tidings*, Oct. 29: This afternoon the Peabody Co. turned water on their wheel, and all the machinery moved as smoothly as master mechanics could make it. The wheel, an over-shot one, is 36 ft in diameter, which gives power to sink the sheft 500 ft. The bolsting works are 30 ft high by 30 long, and are sufficient for all immediate demands. Water from the Y flume will be used to run the wheel, and it is estimated that it will require about 90 inches, miner's measure, to run it. The mine will be pushed steadily forword with the reasonable hope of soon putting it on a paying basis. The shaft at present is 184 ft deep, on an incline. Tomorrow morning a force of 10 men will be employed to commence sinking on the ledge in the bottom of the shaft. The ledge is now 2 ft. thick, is in a slate formation, and shows well in mineral. There are 3 ledges in the shaft, and it is probable that one of them will be followed, as the indications are that there is a rich pay chute not far distant.

Getting Ready for Work.—*Transcript*, Oct. 30: Geo. T. Emery, who recently purchased the river claims of the South Yuba mining tunnel company at Hoyts crossing, Bridgeport township, is making preparations to immediately begin opening up the property. We understand that for the present he will put only 15 men at work, 13 of them to be Chinese. In the course of a few weeks he expects to increase the force to 50, or perhaps 75, and it is said these employees will also be principally Chinese. This is not a hydraulic claim, neither is it owned by foreigners, unless San Franciscans are included under that head.

General Grant Mine.—Work on the General Grant gravel location at Town Talk is progressing satisfactorily. A contract of 75 ft was finished Saturday by Thos. Bennetts, making this tunnel 500 ft long. The contract for extending it 50 ft farther was immediately let to the same party. It is believed gravel will be struck within 150 ft more. The owners of the ground are J. J. Ott, Phil. Richards and Wm. Richards of this city, and Mr. Bennetts of Gold Flat. They have already been at work there nearly 3 years, and so far have not got a color. Their tunnel runs into the ridge from the north side, and Tremaine & Co. are pushing for the same channel from Suttoa's ranch on the south side. The lead hes already been developed on Gold Flat, at the claim owned by Jas. Kitts. During a mouth's run recently, while water could be obtained, the gravel paid $3 a day to the man.

Rich Gravel.—Nevada *Herald*, Oct. 30: Thursday afternoon Louis Seibert, who lives on Deer creek just below town, while engaged in moving a large bowlder from a piece of land, discovered beneath it quite a deposit of gravel. Some years ago Scibert had mined on the ground, and it had paid well, so he concluded to prospect the gravel. From 4 pans of it he obtained over $2. The deposit is not very large, and Seibert says he intends to pan it all out.

The Eagle Mine.—Nevada *Herald*, Oct. 29: It is expected that by the 5th of next month a crushing will be had of 30 tons of rock from the Eagle mine, situated near Pine Grove cemetery. The rock that is now being taken from the mine is very rich, and from the prospects obtained it is believed it will yield as high as $75 to the ton. The ledge is 8 inches wide, and everything indicates that the chute is about 200 ft long. At present the mine is being worked by parties who have leased it on conditions. Mr. Wm. H. Smith, of this city, who is the owner, has no present intention of disposing of the property, but says he finds this system of prospecting less expensive than the manner in which he has previously worked the mine.

SIERRA.

Brush Creek.—We had the pleasure this week of a visit with R. Gillis, Esq., superintendent of the Brush Creek quartz mine, at the Mountain house. He said 3 months will be required for pumping the water out of the 850 ft shaft. Then the progress of development will be rapidly prosecuted. The company is incorporated.

Mines Sold.—The Highland Mary has been sold for $100,000, and Ohio $225,000—all of Wahoo.

Ruby.—The Ruby heading is in hard rock, so much so in fact as to require no timbering.

NEVADA.

WASHOE DISTRICT.

Overman.—*Enterprise*, Oct. 25: The drift on the 2275 level has been extended 22 ft. We struck a small stream of very hot water, which makes the drift very hot. We have re-timbered 30 ft of the shaft near the surface. The Forman shaft has been sunk and timbered 15 ft; total depth, 2,100 ft.

Potosi.—Work on the 2400 level has been suspended, and the air from the blowers turned into the Savage drift, to aid in removing the bulkheads and to allow of other work in that drift, as when that is opened it will materially aid the work on the 2400 level.

Alpha.—Have been engaged the past week making repairs on hoisting machinery, and operations in the mine are necessarily suspended until these repairs are completed.

Consolidated Imperial.—Operations in the mine are temporarily suspended on account of the stopping of hoisting engine and surface machinery for repairs.

Gould and Curry and Best and Belcher Shaft.—The joint west crosscut, 2300 level, is in a distance of 40 ft. The ground is hard and requires no timbering.

Chollar-Norcross-Savage Shaft. — The hydraulic pumps are running steadily at 9 revolutions per minute, easily taking all the water. There was no increase of water to speak of when the bulkhead in the Savage drift was blown out.

Caledonia.—We have finished re-timbering the shaft. Re-timbered 105 ft. The pumps have run an average of 7½ hours per day, consuming 4 1-7 cords of wood per day. The Forman shaft has been sunk and timbered 25 ft; total depth, 2,100 ft.

Sutro Tunnel.—Prospect Drift on the vein at point 4035, South Lateral—The east crosscut has been extended 11 ft, making the total distance of the crosscut 31 ft. The face of the crosscut was still in vein porphyry when work at this place was discontinued and resumed in the drift. This drift has been extended 11 ft, making the total distance from the south lateral tunnel 124 ft. Its course is along the west wall of the vein.

CANDELARIA DISTRICT.

Northern Belle.—*True Fissure*, Oct. 29: In the first level, near the center of the mine, a body of ore has been opened showing a width of 2½ ft, which looks quite promising for the future. The intermediate level, between the first and second levels, on the hanging stope, shows a very fine body of ore 10 ft wide, and of very good grade. The same level, between the second and third levels, looks fully as promising as last week. The other shaft levels show no material change. The levels above the edit present about the same appearance as at time of last report, and are yielding as usual. There are being extracted and sent to the mills about 80 tons of ore daily. Both mills are running steadily; Mill, No. 1, on half time. Bullion shipments for the week ending Oct. 20th, amount to $10,935.51; and aggregate $67,634 00 on October account to the above date.

Mount Diablo.—Winze, No. 1, shows no change in the bottom. In the north crosscut, 40 ft above bottom of this winze, the ore has been followed to the east, but at present there is only a small streak of little value. The north crosscut from winze, No. 3, is in 55 ft and shows a black ledge formation in the face that looks favorable. The east drift on the third level shows no special changes. It has given some very good bunches of ore during the past week, and an advance of 12 ft has been made. The rest of the mine shows no change worthy of note. Winze from the east drift, second level, is down 23 ft. Winze in gulch is down 147 ft.

CHERRY CREEK DISTRICT.

Exchange.—White Pine *News*, Oct. 20: J. H. Roberts Supt. of the Excheage Co., who has been in New York for some time, has returned to Cherry Creek. Mr. Roberts' object in going East was to make arrangements with his company for the erection of additional reduction works for the ores, and a more extensive working of their mine, which he has succeeded in doing. He has commenced to make the contemplated improvements, which, when completed, will greatly increase their bullion production. They will also open up their large ore body below the water level, which has heretofore only been worked to that point, though explored for 600 ft in length,

ESMERALDA DISTRICT.

The Cortez Mine.—Esmeralde *Herald*, Oct. 27: Work is progressing favorably in all parts of the mine. The lower tunnel is in good blasting ground and is being pushed to the ledge. The incline sheft is being driven down as fast as possible. When the lower tunnel and incline shaft reach the same point in the ledge, we expect to see lively work on this mine. The carpenter shop is finished and the coal house is now in course of construction. Everything in and about the mine is running very smoothly under the able management of Supt. Wells and his assistant, Foreman Murphy.

The Centennial mine is looking just splendid, and, as J. B. Hiskey expresses it, is certainly a "big little mine."

EUREKA DISTRICT.

Struck Water.—Eureka *Sentinel*, Oct. 29: Water has been struck in the new shaft of the Satelite mine at a depth of only about 40 ft. It came in so strong thet the contractors had to abandon the work of sinking for the present. Water so near the surface is unusual in this district. It is explained on the theory that the shaft was started in shale instead of limestone. The shaft was designed to tap the ledge on its dips.

The Richmond Superintendency.—So far as known no person has been selected to take the place of Mr. Rickard as superintendent of the Richmond. The general impression seems to be that some one will be sent out from England. In this connection it may be stated that John B. McGee is reported to have made application through Manager Probert for the position. Mr. McGee was the old Supt. of the Richmond, and handled the immense property with great ability and success. He is one of the best smelters in America, and is altogether a first-class business and mining man.

Banquet to Supt. Rickard.—The bead officers of the Richmond Co., with A. E Titus at their head, are to give Supt. Rickard e grand banquet at the Jackson House on Wednesday evening, Nov. 9th. Mr. Rickerd retires from the control of the property with the good will of all who have been associated with him. The proposed banquet is tendered as a mark of great esteem entertained for him by his subordinate officers. Mr. Rickard is also highly respected by the community in general.

Coming to Examine.—A prominent western mining man will shortly visit Eureka to examine a Prospect mountein mine with a view to purchasing it for San Francisco parties. There ought to be 20 Eureka mines on the San Francisco Stock Board. The district has a splendid reputation, and the stock of promising mines should sell readily at fair figures. Besides the assessment plan is the best system yet devised for developing a property. Our miners who are unable to prosecute the work of development should incorporate, distribute the stock and call for assessments. This is the true way of getting down into the bowels of the earth.

No Truth in the Report.—It has been reported on the streets that both furnaces at the Eureka Con. works were about to be shut down. We learn from the best authority that such is not the case, and that at least one furnace will run all winter.

Eureka Tunnel.—*Sentinel*, Oct. 30: The south drift shows marked improvement. It has rich ore in every direction. It is being driven about two ft a day. The ore is as strong, and presents as many indications of permanence as at any time since it was discovered. Sinking the winze will be resumed to-day. Some days have been consumed at this point in putting in a windlass and ladder. The windlass was got in shape yesterday afternoon. Five or six men are kept sacklag ore. The teams are running regularly. Mr. Porter, Gilmer & Salisbury's mining expert, made a thorough examination of the mine two days ago. He was highly pleased with the ore body. He expressed the belief that it will prove to be one of the largest deposits ever found in the State.

PUEBLO DISTRICT.

Copper Mining.—*Silver State*, Oct. 22: J. C. Wear has gone to his copper mines in Pueblo district, with a wagonload of supplies. Some 5 or 6 men are at work on the mines, and will continue prospecting there during the winter. Mr. Wear says there is now sufficient ore in sight to warrant the erection of a smelting furnace; but those who are associated with him thought it advisable to develop the mines this winter, and in the spring build furnaces to smelt the ores. Those copper mines were located years ago, and Mr. Wear obtained a United States patent for them, but they have never been worked to any great extent until this fall. There is abundance of wood and water in the vicinity, so that furnaces can be run without much expense.

ARIZONA.

Bullion Shipment.—Arizona *Miner*, Oct. 29: The proprietors of the Silver Belt mine, Agua Fria district, are turning out bullion in large quanties and shipping the same to San Francisco. Last week 6 tons were sent forth and a like quantity awaits shipment at the smelter. The furnace will continue in operation for a long period and at least $50,000 will have been shipped before closing down for repairs. The Belt is one of the most promising mines on the Pacific coast and some of these fine days will sell for a million of dollars.

The Mammoth.—*Penal Drill*, Oct. 29: This mine is situated about 1 mile to the north of the Queen mine. It is showing up finely, as development proceeds. There are 4 ledges passing through the claim, 3 running north and south and 1 east and west. Two shafts have been sunk at the intersection of 2 ledges with the east ledge. At a depth of 40 ft they show high-grade ore, several pieces of rock averaging $150 and some as high as $500. The ore is as near free milling ore as can be found in this district. The ledge measures 20 feet, with a pay streak of about 4 ft in width.

The Solferino, formerly the Hope mine, is what may be called an extension of the Mammoth, for the same ledges, 3 in number, seem to pass through it. One of the ledges is from 30 to 40 ft wide, carrying high-grade red and grey carbonate ores of a superior quality and in large quantity. All the ledges prospect well. On the main ledge a shaft has been sunk 45 ft in depth, showing fine carbonate ore from top to bottom. Besides the 3 main ledges there are cross ledges. Assays of the ore average $140 a ton, silver, and a few dollars in gold.

Reported Sale.—Tombstone *Epitaph*, Oct. 27: It is reported that the property known as Smith's ranch, at the mouth of Copper canyon, near the south end of the Huachuca mountains, has been sold for $5,000. This is one of the most romantic pieces in southern Arizona. The mountains rise abruptly upon both sides of the canyon, being covered to a great extent with live and black oak timber, and higher up the canyon with pine and fir. There is a beautiful never-failing stream of water, fed by living springs that burst out of the sides of the mountains. The mesa running down to the San Pedro for a mile or 2 is beavily timbered. It is a magnificent place for a summer resort. In the season of growth Mr. Smith has always had the fluest of vegetables and melons. It is said there are very rich copper mines in this canyon, and that this purchase is in the interest of a strong company, who will enter upon the development of that locality.

COLORADO.

Berlin.—Silver Plume *Coloradoan*, Oct. 22: This lode on Hanna mountain is a relocation of Robert Bros. & Co., and shows from 8 inches to a ft of quertz, through which galena and a large share of gray copper is very liberally scattered. It is considered an exceedingly good prospect. Depth only 10 ft.

Baltimore Tunnel.—Mr. Moore, foremen, informs us that there are about 40 leases at the present time working on the company properties, and all of them are taking out pay ore. Their dump which is now on the ground of the old toll-road, is aver 90 ft high, to which a new track has been laid since the fire.

Bismarck.—Two of the owners are working from crosscut No. 3, and the third one will join them next month. They commenced stoping about the first of the month, since which the ore has been increasing both in quantity and quality as they have ascended with the stope. A mill-run from the lower part of the stope contained 100 ozs silver per ton; but the ore they are now taking out they expect to run much higher.

Dives-Pelican.—The lease of Phillips & Co. is on the Unicorn about 30 ft below the tunnel level and east of it. They have been at work only 2 weeks, and are stoping up the tunnel level, having from a ft to 18 inches of ore. An assay of what was thought to be an average sample of the same carried $70 ozs. Four men are at work taking out a ton and a half a week. In the main shaft the company has struck 8 inches of low-grade ore.

Backbone.—The Backbone Mining Co. were found on a late visit of the mining reporter to thet property, engaged at moving the whim down to a level with the dump for the more convenient hoisting of ore. For the past 3 months they have been busy re-timbering shafts, cleaning out drifts, etc., for the more thorough ventilation of the mines and putting the mine generally into a shape for extensive work the coming winter. The lode through all its openings shows a continuous streak of ore from 4 to 8 inches wide, and when properly opened ought to be one of our best ore producers.

IDAHO.

Rich Seam.—Idaho *World*, Oct. 25: A very rich seam was struck the other day in the Sub Rosa, about 120 ft below the surface. It varies in width from 6 inches to a ft. The vein is probably a spur of the main lode. If not, the main ledge is split, with a "horse" between. This new vein has considerable more dip than the one previously worked, which indicates that the 2 come together nearer the surface. A crosscut was run into the old works—a distance of 35 ft. If the 2 veins have been separated by a "horse" they will no doubt come together deeper down. It matters but little whether it is a spur or feeder, or whether it has been split off from the vein. There is a good body of ore that is more than ordinarily auriferous, and the owners don't care what direction it takes or what it will turn out to be, so the vein holds its width and the pay don't "peter."

Ketchum Smelter.—Wood River *Times*, Oct. 26: A half a dozen teams loaded with bullion produced at the Philadelphia M. & Smelting Co.'s works at Ketchum, passed through yesterday, on the way to Blackfoot, whence it will be transferred to railway cars for shipment East. The smelter is running smoothly, producing from 15 to 18 tons of bullion, averaging 245 ounces per ton, per day. About 75 tons of bullion have been produced, of which about 50 tons have been shipped. As the bullion is of comparatively low grade, it is evident, that none of the ores from the company's mines have been run through yet, those ores carrying from 400 to 1,000 ozs. per ton.

Jay Gould.—The best showing of Bullion just now is undoubtedly made by the Jay Gould mine. This property is being opened up in a systematic manner, and shows improvement with every foot of progress. Up to the 2d of October the Jay Gould mine had yielded 245 tons of ore, which sold in Salt Lake City brought $34,300, or an average of $140 per ton. Much of this was surface ore, however, and is, therefore, no criterion of the value of ore in depth. Since the 2d of October very large shipments have been made.

MONTANA.

Notes.—*Inter-Mountain*, Oct. 20: At a depth of 200 ft a west drift has been started on the Morning Star which has penetrated the ledge for a distance of 14 ft. The 325-ft east drift of the Cannon has reached the end line of the claim, and a drift west has recently been started. The stopes are all looking well and are producing monthly about 500 tons of ore, which is sold to Mr. Williams, at the smelter. In the Magna Charter a very large mining force is employed in the various levels and the ore output is now about 40 tons per diem. A station is being cut out at the 300 level and sinking will be resumed in a few days. The machinery has been giving some trouble lately, but the necessary repairs have been successfully made. The Alice is still closed down awaiting the completion of the repairs to the hoisting works boilers which latter have been in continuous operation for 33 months. Mining operations will be resumed in about 3 days, and in the meantime the mills are running on ore reserves of which about 7,000 tons are on hand.

Silver Star.—Butte *Miner*, Oct. 27: From a gentleman who has just come in from Silver Star we learn that the Orecn Campbell mine is being opened under the superintendence of Mr. Price. A new shaft is being sunk, and the mine is being put in thorough working order. The erection of a new mill is also contemplated. In the Ajax mine some good ore has been struck. The strike was made in their western working, which is running under the tunnel of the Mutual Agreement mine. The Broadway is opening out well. A large body of ore has been struck in the 75 level, of a higher grade than before taken out and free milling. Indeed the prospects of the Broadway Co. look very favorable in every direction. Under the prudent guidance of Prof. A. E. Walton they can scarcely go very far wrong. The Broadway Co. has been at work a short time, and has already had 2 runs. Prof. Walton returned last evening with the second retort, which is a large one and has been deposited with Donnell, Clark & Larabie. The English Co. have cause to congratulate themselves that they succeeded in obtaining this valuable property, and great credit should be given to the parties who so skilfully negotiated the sale in their interests. The other favorable circumstance for the future of the Broadway mine is the fact that its present management is carrying on operations in so intelligent and energetic a manner. The activity of foreign capital should excite other mine owners to develop their properties. We understand there are other good mines in Silver Star which will pay well for the investment of a little capital. The graders of the Utah & Northern road from Dillon to Helena are now at work at Silver Star.

NEW MEXICO.

San Pedro.—*News and Press*, Oct. 22: A 4-horse coach will soon run from Wallace to the San Pedro mines.

Water Canyon.—Mines in the Water Canyon district are being worked vigorously and are looking well. A new town is being laid out.

Dry Washers.—Two machines for testing the placers at Los Cerrillos station are now on their way to that place. They were built by the Hall Dry Amalgamating Co., and are of the capacity of 30 and 15 tons each.

Ready.—The Los Cerrilloe M. & Smelting Co., of which Gov. Tabor, the Colorado millionaire miner, is president, has taken hold of the old smelter at Cerrillos station, that has long been lying idle, and having salaraged and refitted the buildings, overhauled the machinery and added improved machinery, is now ready for business on a large scale.

New Smelter.—The Shakespeare Con. Smelting Co. is erecting a 25-ton smelter half a mile from Shakespeare, in Grant county. When completed it will start up on custom work.

Items.—The mines about Shakespeare are looking exceedingly well, and developments bring forth a better class of ore than near the surface. In the Last Chance mine a double-compartment working shaft has been well constructed and development systematically prosecuted. Steam hoisting works have been purchased in Denver, and proper machinery will be duly erected. There are 1,800 tons of ore on the dump. The Vida mine's shaft, down 120 ft., will be relieved of water by a steam pump. A new working shaft is now going down. The Atwood has a steam hoister, now utilized to crush the ore, that is sacked and shipped to Denver. It is good smelting ore classed in three grades, the lowest showing up handsomely. A daily stage line runs to Silver City, and a stage twice each day to Lordsburg, on the Southern Pacific R. R. The town is growing and new houses constantly going up.

Monte Christo District.—Cor. *New Southwest*, Oct. 20: Orent county has now a mining interest in the Mogollons. Owing to many recent discoveries in Little Dry Creek and vicinity, a miners' meeting was held and a new district was organized. The new district is about 10 miles square. The formation in this district is different from that of the Cooney, and the newly discovered lodes differ materially in size and general character. Apparently the leads are true fissures, and with three exceptions are strictly gold-bearing leeds. Repented assays from several claims show an average valuo of $20 per ton in gold.

Golden Copper.—The Golden Copper vein is one of the most wonderful in many respects that has ever been discovered in New Mexico. It has for its hanging wall an immense dyke of quartzite, its other wall being porphyry. It will average 30 ft in width, although attaining 75 ft in many parts, and cross cut plainly for 9,000 ft. The ore is a black oxide of copper, carrying gold. Five assays have given an average of 18% copper and $15 gold. The next copper claims in value are the At Last and Unmatched, discovered by Jos. Sheridan and T. C. Clark. Of the gold lodes in this district the Dolaware and Little Chief are attracting the most attention. This lode is 80 ft in width, running $18 in free gold per ton. It is claimed that capital is hunting large bodies of low-grade ore of easy reduction. Here it is in immense quantities. All of the mines in this district are located on the banks of streams that run the entire year. The hills are densely wooded with pine, oak and juniper. Wagons can be driven to almost any part of the camp, even though no roads heve as yet been made. The distance from Silver City is about 50 miles, leaving the Clairmont road five miles above Duck Creek ranch. We could say in conclusion that the value of these immense fissures, the almost unequalled facilities for working the mines call for attention from men desiring to secure paying properties.

UTAH.

The Horn Silver.—*Southern Utah Times*, Oct. 22: Those who have so long wondered if the Horn Silver would ever pay another dividend, now have the satisfaction of knowing that one of $200,000 was declared on October 1st, and is payable at the company's office in New York city.

Marysvale.—Our correspondent, who just returned from a tour of inspection through the Marysvale region, says that matters there are progressing very slowly, the grade being unfinished. About 75 men are at work, straining every nerve to complete the mill within contract time, i. e., November 15th, but with no apparent prospect of success. By the terms of the contract the mill will have to be in running order at the time specified, or else stand the forfeit of a large sum of money. Assayer Henry, one of the interested parties, said, in a recent conversation at Beaver, that unless the mill was ready to "start up" on the 15th day of November, he proposed to make it hot for the Copper Belt Co. A 5-ton semple of that company's ore sent to the Roef for mill trial, showed very satisfactory results.

Deer Trail.—This mine is being worked by a small force, and is producing nothing in proportion to its capacity.

Crismon Mammoth Mine.—Salt Lake *Tribune*, Oct. 30: Tintic is again taking the position it is so justly entitled to, and a great amount of work has been done in the mines during the season. The California Central, now under construction from Lehi to Tintic, will soon reach this mining district, and a boom of extraordinary size may soon be looked for in this meritorious section of Utah. The Crismon Mammoth, which has long had the reputation of one of the largest gold and silver mines in the United States, is looking as well as ever. It gives employment to 32 men, and is showing a body of ore 80 ft in length and 30 ft in hight, assaying from $35 to $300 in gold and silver, while the gulf and middle workings show thousands of tons of baser ores, assaying $65 gold and silver, and 25% copper. Stoping continues in the north drift in a big body of ore. In all the levels and drifts large bodies of rich ore have been uncovered, all going high in gold and silver. The mine was never in better condition than at the present time, and there is ore enough in sight to keep a 100-stamp mill busy for years

Precious Metals in the South.

Doubtless there are 50,000 msn from the Southern States who are seeking fortunes among the mineral regions of the Rocky mountains. Meny are laborers in great bonsnzas at from $3 to $4 per day; some are prospectors, and meny are huyers and speculators in mining properties. In Daniel Boone's time, and etill later, eays the "History of Kentucky," the Indian tribes of southeast Kentucky and eastern Tennessee brought very large quantities of native silver to ths whites to trade for goods. It had been smelted or redneed into rongb bullion by some process nnknown to the whites. So, is it not etrange that Kentuckiane ehould not have taken this hint from the history of their State, and engaged experienced prospectors to locats the veins which produced that silver?

The other Southern State intereeted, and wbose citizens and capitelists are to be found in every mining camp, is Missouri. The St. Louis emelting and rebning company erected the first emelter and worked the first ore at Leadvills, Col. The cream of that great camp was carried off by capitalists of St. Louis before stock tricksters began tbeir mine killing operations there. Texas has thousands of operators in Arizona, New and Old Mexico. There are several mining companiss of Florida operating in Colorado, New Mexico, California and Arizona. Louisiana is spareely represented. There are two organized companiee in New Orleans. One of them, tbe Hanselman Willet-Muncy company, has 17 mines and fractions of mines in Custer county, Col. Edward Enderle, of this city, is on the ground superintending the work. Thomas Hunton, attorney-at-law, and associates in New Orleans, are interested in mining properties in different parts of the West. The above ie introductory to demonstrats how men will go so far away to invest in mining, since now it is down to a solid businsss basis, wbile close at bome are the same untold millione in hills and mountains—precious metals awaiting man's bsnd with picks and sbovel to explore and extract them.

A prospector wbo has bad many long yeare of toilsome experience prospecting in the great mineral regione of tbe far away west, a few montbs eince passed three months surface prospecting in Nortb Carolina, east Tennessee and southwestern Virginia. He has obtained a copy of a very old map, copied from an older Spanish map. The map represented this region as almost solid in lodes or veins and deposits of precione metal. He found veins out-cropping clearly and plainly, witb perfectly defined walls. Many a mountain of granits rock had veins of mica in it. Tbis mineral is at present in as pressing demand as gold. The largest piecee bring fabulons prices for windows of vessels of war and steamships. Tbose from 2 inches wide to 5 or 6 to 8 inches in length, a lasser price for tbe coal stove industry, still an immensely profitable one. Ths third class is a great body of the vein—fully 80 % of every vein—which comes out broken into fragments. For thie the demand is greater than the supply, and must remain so as long as it is coming into general use as a lubricator. The railroads pay eo mucb for it that, as the supply is not equal to their demaad, other peopls cannot afford to pay for it as a lubricator. The axles of tbe swifteet lightning trains lubricated with tbe micaceous lubricator neither heat nor wear away. Since this discovery was made, the Rocky mountains, supposed to bold all minerals excspt iron and coal that are valuable, have been prospscted over and ovsr, especially near the Arkausss river above the grand canyon of the Arkansas and Royal gorge. Tiree claims were found in an uncertain, broken condition in 1876. They cannot be made to yield well or much. Twenty months ago a 14-inch vein was discovered south of Santa Fe. It sold for $19,000 cash when 10 ft. deep. It will be seen by the notee below that North Carolina is supplying about all the world is receiving, and yet cannot furnish enough. It is wanted as a lubricator for all kinds of machiues.

The Nortb State Mining Co., of North Carolina (English capitalists), have a vein of mica eigbt ft. in width, four ft. of which is solid mica. This is of the lightest color, free from iron etains and very flexible. This company owns 4½ miles of fine iron ore, which lies in hede from 10 to 40 ft. wide. They have 125 men at work on the iron ore. Tbey are building a railroad from Statesville througb Salisbury to their mines. They are erectiag smelters and mills. One mill was completed early in August, and they began orushing August 20th.

The Conrad Hill copper and gold mine people near Salisbury are pushing work, and are advertisiog for 300 more hands. In the same vicinity, the Silver Valley mine is working 75 hands.

Tbe Baltimore and North Carolina mining company are erecting a mill. Thie property is five milee west of Aehboro. The ore is quartz, mining up to $80 in gold per ton. (The average yield of gold of tbe Black Hille for eight yeare has been $7.50 per ton.)

The Hoover Hill gold mine ie owned by Englisb capitaliets. The ownere are driving ehafte and tunnele, constructing tramways, etc. Their new mill will be at work by October 1st. Tbe Atlas and Bame mines, near Salisbury, compriee 1,351 acres of ground, purchased by Mr. Leopold Graf, a capitalist of Newark, N. J. This ground ie proven rich; it liee between Gold Hill and Dutcb Crook minee.

Tbe Clarissa mica mine, near Bakersfield, county eeat of Mitchell county, ie a 4-ft. vein of mica, owned by Mr. J. G. Heap and John Clapp. They have several shafte, the deepest of which is 325 ft. They are working a very large force, running six ehafts, which average 85 ft. The same parties own and are working the Sink Hole mica mine, and the Cook mica mine, all in the same vicinity.

The Reed gold mining company, of Cabanus county, are finding, in washing, nuggets weighing from 1 to 5 ounces. Thie county furnisbed the Indian tribes of a large region of country, gold for their ornaments. Every creek aod strsam bottom of that county ehows plscer gold mines. The Backs mine, 10 miles from Lexington, is being worked with quite a large forcs. At the Stelle mine, near Salisbury, thsy have struck a rich pocket running into hundreds of ounces in gold to the ton. The Ward mins, near the eame place, is a valuable property.

The Weed mine, recently purchased by Thurlow Weed, is paying well. It is located near Lexington, Davidson county. Without at present mentioning any of the othsr hundreds of properties of North Carolina, these will show far greater development than the Southern people ever dreamed of as going on in the South. North Carolina is bardly tickled as far as her vast mineral wealtb is concerned. Not a thousandth part of ber precious metal-bearing ground has been toucbed. The prospector mentioned above, found precious etones in great abundance near the mountaine and below the mountaine for many miles. Red garnet is more abundant in the valleys and along etreame and in their beds in Catawba connty, than elsewhere discovered in tbe world. Ametbyst, topaz, limpid crystale, opals, and other valuable stones, are abnndant. It requires study and experience to detect tbem, for, like the diamond, all are covered with a rough outside. No more profitable mining field can be found tban western North Carolina, and the field is not confined to North Carolina alone, but Tennessee, southeastern Kentucky, South Carolina, Georgia, Alabama, northeastern Mississippi and Virginia ehow nearly as well. There is more mining machinery in Nortb Carolina than in New Mexico and Arizona togsther to date, and that tells the story. Nickel, platinnm, cobalt, and tbe various argentiferous ores of galena—ores of lead—are abundant also.—*New Orleans Times.*

Yield of Mines.

From the date of the discovery of gold in California, mining bas been eteadily, and for the past fow yeare rapidly, gaining public confidence, and now it is justly regarded as a legitimate, safe business—one of the most important industriee of civilization. When that discovery was made, the great mase of people was incredulous, regarding ths announcsment as a sort of "Arabian Nights," or the tals of "Aladdia's Lamp," revamped and published uader a new title. It is a historical fact, however, that since that day California has produced $1,000,000,000 in gold. Astounding as this statement may appear, it is none ths less true. Tbe same incredulity was manifested about tbe discovery of gold in Aust alia, but, notwithstanding that, ths island continent has produced £200,000,000 in gold; and the grand total productions of bullion from all sources since 1848 amount to $5,862,165,000.

When the silver mines of Nevada were discovered, no oae believed, not even Comstock, tbe discoverer, nor even contemplated the vast treasures etowed away in those inhospitable monntsins; but Nevada has sent out $275,000,000 of silver, and the production of the United States since 1852 has bsen $340,310,545 Then came Colorado, Montana, Idaho, Utah, Arizona, and tbe Black Hills, each baving to stem the tide of popular distrust, to prove by actual demonstration the existence of precions metals in tbeir river beds and monntain ranges; bnt tbey bave given their millions to the commerce of the world.

The fact that one-half of the territory of the United States in mineral-bearing and the mining interest is rapidly assuming colossal proportions and is already of immenee value and importance, demande recognition. The Government has for some time snpported a department of agriculture and it is a question whether the industry of mining for the precione metals, gold, eilver, iron, copper and lead has not grown to be of sufficient worth to be entitled to the same care and assistance which is bestowed upon other and less important vocations. The magnificent resources of thie conntry will never be fully appreciated, and the value of its mining industry never really understood nntil eome great wave of fiaancial disaster threatene the foundation of our national prosperity. Then to find a thousand mines ready to pour ont treasure like water, and a mineral territory large enough to meet the world's demand for a substantial currency, will turn aside the force of the blow eo that if our people are wise in time we may laugb when calamity threatens us with destruction.

The Hardy Prospector.—During tbe past two or three daye we have noticed little partiee of three or four men riding into town on tired eaddle borees, leading jaded pack mnlee. These rough-looking fellowe are the men wbo are keeping up the country by proepecting for new mines. Every dollar they get they earn fairly enough; and in too many cases the fruits of their labore are reaped by others. Long life to our uoble army of hardy proepectors!—*Boise Paper.*

Magazine District.

Since the ricb strike in the Red Rover mine, a good many prospectors have been in tbe vicinity, and several locations have bcen made, which are thought to bs "way up." Previous to tbe discovery of the Red Rover, by old "Rackensack," there had often been prospectors in ths Rsd range, but they always reported no signe of mineral. The ledges throughout this whole region are capped with copper-stained rock, and no one has had the pluck to sink a few feet to determine their character. Thie development of only 50 ft on the Red Rover, discovering a large body of $2,000 to $3,000 ore, will revolutionizs the old method of prospecting here, and from this on we may look out for big strikes. Men have been scratching on the surface with little poll-picks, for years, and the result has been positively nothing. They get an assay of tbe top rock, which seldom exceede twenty-five ounces, become disgusted and "throw up" the prospect. There are many msny large ledgee of this character in tbis and Cave Creek districte, which have been located year after year, by different parties, but which have never been even worked to the amouat of a year'e assessmsnt. Many of these will now be sunk on, and some will undoubtedly run to eilver, inasmuch as it ie becoming very well demonstratsd that the lsrge copper prospects througbout Arizona ars often hut cappings of eilver. Among those who have lately taken locations on the Red Rover ledge are Dr. Jones, Frank Shaw, Major Chaffee, Phil. Sheridan, Prof. Flemming and others, all men of uudoubted judgment in mining matters. The numbsr of extensions taken on this mine is astouuding, though it is whispered that every location within a radius of three milee is claimed to be an extension. There is no doubt, bowever, that a mineral belt can bs traced, both northeast and soutbwest, from the Red Rover for several miles. Cram mountain is a fine mineral locality, about four miles to ths southwest, wbere a group of large ledgss of copper, glance, gold and low-grade silvsr have been gouged at for the past 10 years. Old Rackensack is oow prospecting a little to tbe northward of Wood's station, and has discovered a ledgs of three to fonr ft. wide of rich copper glance, near Rodgers' Spring. The formation is fine porphyry. He desires to get some ons to take a working interest in it. The weather is unprecedentedly hot hers for tbe season.—*Arizona Gazette.*

Ocean Wave Power.—The Directors of the Swalee Ocean Wave Power company, Messrs. O. F. Willey, P. H. Csnaven, C. J. Hutchinson, W. C. Doane and John Lyons, recently petitioned the Board of Supervisors for permission to open the public streets for the purpose of laying down mains and pipes for carrying salt water, for compressed air and for electric uses. Their petition was referred to the Committee on Water and Water supplies. It aunounces that the corporation wss formed for the purpose of furaishing motive power by mesns of the action of ocssn waves and tides, with which to supply salt water to the city for watering ths streets, flushing the sewers, supplying public and private baths, extinguishing fires, and for other municipsl and private purposes, for driving machinery, compressing air and generating electricity, and for all manufacturing and commercial parposes. The projectors bave exhibited drawings of their proposed machinery. Ahout 15 years ago Mr. J. S. Silver urged a petition similar to the one aoove spoken of.

Fitzgerald, Turquois District.—Recent mill runs from the Fitzgerald, owned by Hortong, Sorin and others, have attracted considerable attention to the northeastern end of this district, and we hope will result in giving a etert to that camp, than which oone in southern Arizona ie more delightfully eituated. But little development haa yet been made on the property, but three millinge hy the Boston mill of ton lots proves the ore to average over $70 to the ton. The ore is white and red quartz filled with gresn horn silver and cbloride. Another promising prospect is the Silver Cloud, owned by Packard, Leavenworth and others. Work on tbis property was resumed tbis week and the shaft and dump ehow a fine ledge of pay ore.—*Epitaph.*

The Lead Market.—The New York *Mining Record* of the 15th says: The demand for first-hand parcels has been quite moderate during the past week, and but few transactiooe have transpired. Consnmers appear to have supplied their preeent requirements in a great measure, and are not disposed to further replenish their etocke. Common pig has been offered and eold at 5 1-5 to 5¼ cents, which ia the present market value, and corroding is nominally held at 5.35 to 5½ cents, but we do not bear of any sales.

The *Enterprise* now heare more talk about Candelaria thaa eny other outside camp. That they have good minee there, both prospected and unproepected, ie well known, but heretofore the place bas been difficult of accese. Very soon the Carson and Colorado railroad will be rnnning to that camp, bringiug it out of the wilderneee at once, and uniting it with all the eources of eupply, as regards machinery and all elees

Hydraulic Mining a State Benefit.

The miners believe that tbe suits bronght against them are nothing more than a gigantic scheme to enrich a few lawyers. One suit would dispose of the merits as well as 20. Sacramento has fallen in line with a reteiner of $12,000, and other countiee are being pressed to follow that example. The State Engineer assessed the damage of 30 years mining at less than $5,000,000. An insignificant amount compared to the hundreds of millions of wealth extracted by our hydraulic minere, and from whicb ths agricultural population has derived great bsnefit. And further, to offset this damage, large areas of land heve been reclaimed by slickens, wbich is notably the case in thie county. Thirty-two companies were sued on the Yuba and only four injunctions served, and those on companies supposed to be owned abroad. Fourteen hundred msn, mostly having homes and families, were thrown out of employment. Minere believe that if proper influences and money are used, exemptions from service of injunction can be secured, and therefore do not feel that confidence in the law wbich exists in other communities, especially as Judge Keyser wae elected on the issue of bis well-known hostility to the miners.—*Georgetown Gazette.*

Salmon River Mines.

A member of tbe Klippel company arrived in Lswiston last Monday, and informed us tbat the company had etruck pay gravel—on the scene of their wing-dam labors on Salmon river—of sucb a character that they were taking out $2,000 every 24 hours, and that he was on hie way to Portland to order tho necessary machinery to work the diggings on a more extensive scale.

There are, along the banks of the Snake and Salmon rivere and their forks, hundreds of these claims, as rich and equally adapted for work as the Klippel.

We can now announce to the world tbe positive fact tbat no country presents more or better inducsments for the profitable investment of capital in mining enterprises than north Idaho. It is, in fact, a common practice among foot-loose and dead-broke miners to make a grub stake for tbe next prospecting season with a rocker planted on the nearest Snake river bar; $4 or $5 are easily washed in as many houre by this simple mining process, but the honest miner scorns to make what be calle "China wages" by China miniog, and the rocker is only used when be is desperately bard up. But the gold is there all the eams.—*Nez Perce News.*

Costly Idleness.—Those four months during which the hydraulic mining companies enjoined hy Judge Keyser, permitted their properties to lie idle, composed a very disastrous period. The North Bloomfield, Excelsior and Milton companies each sustained losses approximating $100,000. The Blue Tent compsuy suffered to the exteut of about $50,000, aod the Union compsny not less thsn $40,000. The American company were compelled to let their claims be sacrificed under the sheriff's hammer, and their loss cannot be reasonably put at a lower figure than $50,000; for had tho bugaboo of an injunction not put in aa appearance, the wreck would, we are told, not bave occurred. The 21 other hydraulic companies made parties to the suit, although not enjoined with the above corporation, daily expected the wrath of the plaintiffs to be directed at their own heads, and the dead-lock extended to nearly all of them; so they hesitated about laying in their supplies aud making other preparatione for the winter'e work. Their total loss will exceed, as shown by a careful estimate, $300,000. How much tbe employees in the various mines, and the mercantile and other branches of industry carried on the hydraulic mining regious have suffered in dollars and cents, cannot be arrived at, although the amount is certainly large. To offset all this is a bond of $25,000 filed by the plaintiffs.—*Nevada Transcript.*

Sunny South.—After we bad gone to press, a week ago yeaterday, we received a call from Mr. M. H. Power, of Sunay South. Sunny Soutb is emphatically a mining town, has a population of between 100 and 200, mostly men, aud yet the place hee aever had a policeman or a constable, and has never needed auy. In spite of this showing the Sacramento *Bee* ineists in referring to the miners as a rough, rowdyish, uncouth, boisterous and lawless set. Nothing could be further from the truth. As a rule, miners are more than ordinarily intelligent. They read the papers and pay for them. They are particularly well posted. They are loyal to the core, and they are respecters of law aad order. No man ever treated a miner well and received ill treatment of him in return.—*Placer Herald.*

Quick Work.—A diepatch of the 25th ult., from the Atlanta cotton expoeition, eays: "Nine governore are here and thoueaods of visitors to witness tbe opening of the exposition. Tbe visiting governore were welcomed to the expoeition in the afternoon, Gov. Colquitt delivering the address. Several governors reeponded. The crowd wae overwhelming, and great enthueiaem was manifeeted. The featnre of tho day wae the making of two euite of clothes—one for Gov. Colquitt and one for Gov. Bigelow—from seed cotton picked at 7 o'clock in the morning. The suite were worn at the reception in the evening."

Abandoned Mining Districts.

It is nothiag against a mining district that it was ahaadoned hy the original discoverers. Tbis fact is fully demonstratsd by half a dozsa districts iu Nevada. Ws note that Como, in Lyon couaty, is coming to the front as a bullion prodacer. Ia 1863 a prosperons commaaity was located at Como. A town of considerahle sizs spruog up, aad the place bid fair to be as permanoat as auy of its neighhors. Sahsequently tho town went dowa, aad ia a few years there was ant a man or house left to iadicate its former size. It was revived the past season, aad now has a population of several haadred. A quartz mill has hesn crected, aad several valuahls miaes are ia course of development. Who knows but what ouce-abaadoned Como may becomo oue of ths most importaat mining camps in the State?

White Piao has a history almost ideotical, oaly oa a graader scale. Thsy had the biggest boom of all the booms in the White Pine, but it gradually dwindled down until it hecame very thin, the population falling off from 40,000 to less than 300. Within the past year several important mining euterprises have been inaugurated there, aad we shall be disappointsd if her population does uot increase the comiog season.

Eurska District was discovered in 1865. It wae as good as ahandoned until 1880. Now it is the great miniog center of Eastern Nevada, prodncing ananally millioas of dollsrs, and supporting a population variously cstimated at from 6,000 to 8,000.

Bodie, the liveliest camp in California, to use a prospector'a term, was struck ia 1860, oaly a year later than the Comstock. It lay comparatively dormant for aearly 20 years.

Geaeral Coanor'a troops mado locations in Pioohe as early as 1864, but it was not until 1869 that the wonderful mines of that section hegaa to attract geaeral attention.

Aad so we might go on enumerating many other localities, but the above will suffice to show that it is not alwaye eafe to estimate the capahilitiea of a mining district uatil it has heen thoroughly tested with capital aad muscle. —*Eureka Sentinel.*

A Novel Fishing Device.—A new aad very destructive fishing device ie reported from the Columhia river, Oregon. It consiets of a jetty of rocks huilt out from a point on tho shore of the river, outside of which is a plaaked sluiceway, in which an undershot wheel with large taak hackete revolves. The sluiceway is built when the river is at ite lowest stage of water, aad the wheel is hung so that it can be raised or lowered as may he dcsired accordiag to etage of water. The instiact of the ea'mon is to run up the river aloagside of the haaks, instead of mid-chaaael. By thie the fish can take advantage of the eddies helow jutting points of land. On these projecting points the Iadiaas have, from time immemorial, taken salmon in large numhers hy usiag dip aets. The jetty, built out from the poiat, makes a larger and longer slackwator hehind it, and the aalmon roundiag the point rash iato the sluiceway to get up the river. In the sluiceway the wheel, which revolves in the current, is guaged so as to sweep within n foot of the hottom, and the salmon are scooped up in the huckets, which latter let out the water as they ascend. On the wheel descending the fisb are thrown out into a trough or gutter leadiag to a pen helcw, where they remain nntil taken away to he canned. The arrangement of the slnice, wheel, etc., is a most successful one, the catch of aalmon running from 1,500 to 4,000 per day. There is virtually no expense in taking the fish, save attending to the pen. A fatal objection to this device ariaes from the fact that it scoope up and kille little fish ae well as hig onea, and as yet no provision ie made in connection with it for the escape of tbe former. Unless the the threatened wholesale killing of salmon too small for canniag is prevcnted the supply will he eatirely cut off, and the entire canning industry destroyed, if the wheel comes into general use.

A Locomotive Attachment.—The model of an improved locomotive was recently exhihited at the shops of the Lake Shore railroad, in Cleveland, Ohio. The improvement consists of an attachment to he placed on the side of the hoiler, and ia intended to do away with the eccentric and cumhersome machinery connected with it. The arrangement is pronounced very simple hy those who inspect it, and locomotive engineere praise it highly. Mr. Anderson, of Painesville, is the inventor. It is claimed that the new arraagement can he applied to aay engine in ten houre.

A New Device.—Mr. Harris Tahor, euperintendent of the Hartford Eagineering Company, has introduced an ingenious way of fixing a ateel pin in a cast-iron crose-head, hy takiag a steel tube, turning it up true, and eetting it in the sand hefore the cross-head is cast. The gate runs through this tuhe, and in filliag the mold "hurns" the etsel tuhe faet on the cast-iron core. This method has the advantage of having the pin turned and finished hefore casting the cross-head, so that, heyond a little cleaning up, no work need he done on it.

Bears are said to be more ahundant in Butte county than at any time for 20 years. Deer are aleo working their way to the lower ranges, whicb is accepted as a sign of a bard winter.

Useful Information.

Wearing Qualities of Aluminum.—The *Manufacturer and Builder* furaishes the following usaful iaformatioa uader the ahove head: There is no ohjeotion to aluminum for such domestic uses as spoaas and tho like, ou the score of its wearing qualities, which are comparatively very good. This fact has heen experimeatally verified hy Herr Wiakler, a Gsrman chomist. To test in practics ths wearing qualities of aluminum, this chemist had made a number of spoons, rsspectively of silver, pure aluminum and Germsn silver. A spoca of each of the metals ahove aamed was accurately weighed on February 1, 1876, and all were put iuto use under precisely similar conditioas for the period of ous year. They wers nlsced in the same soups, sauces, soar salads and the like, and the servant whose duty it was to wash thsm, was givsn strict orders to cleau thsm saoh in the ssmo manasr. The oleaning coasisted substantially in wiping thsm with a woolsa cloth, washing them ia hot water, aad thsn riasing thsm ia cold. Soda was often put into the hot water, and the spoaas were thus daily subjected to hot acid aad alkaline solutious. The color of all ths metals altered ia time; the alnminnm lost its luster aad became of a dull, hluish-gray color; the Germaa silver also degensrated to a grayish yellow tint; the silver lost oaly in color, hut its luster was uot impairsd. As regards mechsaical abrasioa, ao marked differeace was perceptihle, although after a year's uss the aluminum showed distiact traces of wear at the edges. By accurately weighiag the spoone at the ead of the period aamed, the fact was estahlished that the loss of weight suffered hy the spoon of silver was 0.403%; by the aluminnm spoca, 0.630%, aad hy the German silver spoon, 1.006%. From the above facts, it appears for such domestic articles as spoaas, aluminnm stands wear very well, though not so well as silver.

Underoround Telegraph Wires. — The growiag necessity for placing telegraph wires uadergroand in cities, is eliciting much discussion in regard to some cheap and yet desirahle method of iasulatiag the wiree. A new material has recently bsen hronght to the attention of the public, which is said to he only ahout one-sixth the weight of iroa. It is composed almost wholly of pure carboa, in what form ie not etated, aad so is indestructihle; does not rnst nor change hy exposure, whether in the air or uadergroaad, as is not affected by frost. But the chief virtne claimed for it in connection with underground wires is that it is a perfect iasnlator. It is eaid, too, that the pipes need not he huried very deep in the earth, as they may he of a semi-elastic character, adjustiag themselves to the slight upheaval and depreseion of the gronud through the action of frost or other disturhaaces.

Fires from Electric Wires.—The possihility of firee from electric wires is occasioaiag no little uneasiness among the insurance companies, hut, as would appear, without reasoaiag. True, cahlegrams assert that the fire occurring a few daye ago at the Paris electric exhihition, was due to some wires put up hy the Fox Electric Light Committee of Eagland, but the chsirman of a committee appointed hy the Board of Underwriters some time since, to investigate the whole suhject, is authority for the statement that the committee are fully convinced that if the wires are properly insulated there is less danger from fire from electricity than from leaky gas mains and kerosene oil, and it is their intention to so report.

Imitation Amber.—Considerahle quantities of heautiful ohjeots of artificial amher are now being produced in Vienna. The snhstance employed in its manufacture is chiefly colophony, or resin, ohtained hy decomposition of turpentine, though several other ingredients are used to give it the requisite qualities. The imitation is said to he perfect, and the production has even the electric properties of amher. Ingenions manufacturers have even introduced into the suhstance foreign hodies, insects, etc., to make the similarity more striking. Natural amher requires a temperature of 285° to 287° C. to fuse it, while the imitation hecomes liquid at a much lower temperature.

The English Lanouage.—It is etated that a larger number and greater variety of ideas caa he conveyed with more exactness in a given numhei of words in the English language than most any other. This is strikingly ehown in the matter of telegraphy. It has heen demonstrated that for all telegraphic purpoeee, the Eaglieh language is from 25% to 33% cheaper than the French, German, or any other language.

The old proverh of the prophet, etc., ie illuetrated hy the inventors of thermometers. In England they use Fahrenheit'a thermometer, the invention of a German. In Germany, the thermometer of Reaumur, a Frenchman, is still the most common. In France, and in many other countriee, the Centigrade thermometer, which wae invented hy the Swede, Celsius, ie univerally adopted.

To Utilize Old Rubber.—The pieces are heated in contact with steam, when the eulphur is volatilized and the caoutchouc melte, and ie collected ae a liquid, nsed in preparing waterproof covers, etc.

Substitutes for Timber. — The growing scarcity of timbor appears to he attractiag the attention of visitors everywhsre to tho importaacs of devising substitutes. It is now stated that a houss could be huilt of glass blocks about as cheaply as of granite hlocks. Soms glass manufacturer should make the demoastration. But people who might live in snoh houses should ho carefal not to throw stoaes. It is also claimed that fire-proof houses can be built of cotton aad straw. Ia preparing thsse materials, raw cotton of iaferior quality, the scattered refage of plantations aad sweepiags of factories, are mixed and converted into a paste, which becomes hard as a stone, and thea is callsd architectural cottoa. It may bs made in large slabs, whersby ths huildiog of a house would he rapid in compsrison with the practice of layiag brick aftsr brick, aud at about one-third the cost. For ths other part, wheat straw is treated ia a way already knowa, and converted into pasteboard. The sheets thus prepsred ars soaked ia a solution, which hardens the fihsrs, and are then compressed uader euormous power into beams and boards of any reqnired size, and the effect of the soakiag is said to reader them difficult of combastion.

Letter Stamps.—The iagenuity of mankind in the manufacture of stamps has displayed itself ia 6,000 differsnt kiads. The museum at Berlin contains 5,000 specimens, half of which havs a European origia. Amoag the many kinds of decoration which havs been ased on stamps are coate of arms, stars, eagles, lions, the effigiee of five emperors, eighteen kings, three queeas, one graad duke, sevsral titled rulere of less raak, and maay presidents.

A cheap paint is made for hrick walls hy simply mixiag up good hydraulic cement ia water, aad applying with a whitewash brush. The natural tint is nentral and pleasing, but may readily be varied. This paiat cannot ho washed off hy storms nor peeled off hy the sun.

Asphaltum and India Rubber Varnish.—Dissolve India rubber in a small quantity of refiaed spirit of tar. It takes ahout six hours to dissolve. Asphaltum dissolves in the same vehicle in ahout the same time. This is preferahle to the old plan with mineral naphtha.

Good Health.

Death from a Tarantula Bite.—The Louisville *Courier Journal* of Oct. 12th, says: Oliver C. Waddell, who recently removed to this State from Texas, settliag along White river, in Stone county, was hitten yesterday hy a tarantnla. He was on a hunting expedition in the mountaias, and had camped under a large piae tree. Some time duriag the night the insect crawled in hetween the hlankete which enveloped him as he lay before the fire and hit him twice, once on the fiager and again on the arm near the elhow. He was awakeaed by a tingling sensation in that part of his body, and rousiag himself, discovered the cause and eucceeded in killiag the tarantula. It was as large as tbe hand of an ordinary man. Waddell's hand and arm hegan to swell rapidly, and before he could get to the nearest house, some four or five miles away, tho poison had spread apparently to all parts of his body. It was some time before he conld get medical skill, and when the physician arrived Waddell was found to he heyond hope. He lingered sometime, however, dying in the afternoon. The case is a singulnr one, from the fact that it proves that the tarantula is capahle of inflicting a death wound.

Wood-Splitting as a Remedy.—Some years eince, the wife of a wealthy Tennessee hanker, after trying a variety of remedies for dyspepsia and other ailments, consulted a physiciau noted for plain common sense and small doses of physic. He told her if she would split the wood for the family it would cure her. Woodhouses are unknown in Tennessee, or were at that time, and of course the wood-splitting must he done in the open air. The lady procured an axe suited to her hand, aud applied herself to the task, beginning with a few sticks each day, and increasing the number as she grew stronger. Gradually her ailments all disappeared, and her health hecame exuherant. When we knew her 25 years ago, with a house full of servants, and practically unlimited wealth at command, she still did all the wood-splitting for the family, and hid fair to douhle the half century in age she had already attained. Douhtless, taking hor exercise in the open air had quite as much to do with her recovery as the mere muscular lahor had.—*N. Y. Tribune.*

Comparative Longevity.—The Director of the Bureau of Statietice at Vienna has made eome intereeting reeearches concerning the longevity of women and men in Europe. He finds that out of 102,431 individuals who have passed the age of 30 yeare, 60,603 are women and only 42,628 are men. In Italy 241 alleged centennarian women are found for 141 men of that age.

A Good Disinfectant for the Mouth.—Permanganate of potaeh and hinoxide of hnrium, of each 24 grains, are to he ruhhed up into a mass, with eugar and glycerine, and divided into 144 lozengee. It is said that the uee of these will remove all disagreeahle odor from the breath.

The Improvement of Human Health.

In result of a somewhat large acquaintance with the facts held to iadicate ths state aad progress of "hnman health," I fear my testimony mnst he given to show that the improvement effected hy science coasists in a prolongation of tho passive endurance of life, rathsr than an extension of the period of trne vitality, or any increase of the opportnnity for good work aad real intellectual eujoyment. We may "live" loager, hut our lives are not either happier or more nseful for the excessive eaergy recently devoted to the conservation of health, or this inordinate and laborious means taken to avoid disease and death. It may, doubtless, he posaihle to raise humanity to the levsl of one of tbose scientific toys which approximate perpetual motioa, hut expend their whole force in moving themselves. Whether loagevity purchased at the price of passiag a life-time in running away from death would he worth having, I mnst leave to be determined hy the judgment of tbose who set a value on our so-called sanitary progress, which I, for ons, fail to recognize.

I thiak men were happier aad hetter, and lived nobler livee before the pursuit of health and the yearning for longevity hecame a craze, almost amountiag to madness. What to eat, driak and avoid, what to wear, where and how to live, by what means to avoid infection, to kesp off disease, and to escape death for a few weary and worried years, are questions which so engross the thoughts, if they do not emhitter the lives, of the mnltitude, that the proposition, "Is a saaitary life worth living?" has come to he a subject of serious contemplation, and one which the taxed and harassed community will sooaer or later he compelled to entertain.—*Dr. Granville, in a letter to the Spectator.*

A New Malarial Disease.—The Boston *Herald* shakes in anticipation of a great danger which menaces that city. It saye: "A terrible foe ie marching upon New Englaad. Hie name is Malaria. This mysterious disease is etill a pazzle to medical science, and no satisfactory cause can be assigaed for its origin, although varions theories are advanced. But we must face the alarming fact that the daager is upon us. It ie now acknowledged that, year hy year, the malarial zone is steadily spreading nortbward. Every summer it has attacked new districts whose saaitary conditions were hitherto unquestioned, and thus far it has scemed to come to etay. At the time of the Centennial it made its appearance at Philadelphia and scored its victims hy hundreds. Nearly all of New Jersey is now a den of malaria. It has intrenched itself aloag the Hudson and crossed iato western Vermont. New York City and the shores of Long Island sound are fearfally inflictcd. The past summer ite advance line has appeared in the Berkshire hills and in the Conaecticut valley, Lenox and Spriagfield heing especially marked. It has even come as near as Rhode Island, makiag its appearance in several districts of that State this season. Therefore it is time for us to be alive to tho daager before us."

Treatment of Nervous Shocks.—Tbe true way in all cases of shocks, whether from hurts or frights, is to unloosen every handage that could obstruct circulation, lay the person in an easy position, see that the feet are warm, the room well ventilated; let them lay (it may bs) for hours or even days, and "balmy sleep, Nature's sweet restorer," will do its work hetter than all the stimulants in creation. If, when consciousness return, there is sickness or headache, as the case generally is when the shock occurs soon after a meal—hecause it suspends digestion—the contents of the stomach ferment and sour, to prevent which a good drink of tepid water, and sometimes, the finger placed at the back of the tongue, will produce a vomit and the souring mass thus prevented from vitiating all the fluids. Let this he followed hy another sleep. If inflammation occurs, it can be stayed by a wet cloth, properly regulated as to temperaturo and duration to meet the case—the sense of comfort heing the rule of right.

Ivy Poison Remedy.—A correspondent of a contemporary says: "My hoys have heen great sufferers from ivy poison, one of them to an extent heyond description, aud visited hy many physicians two or three times a day without any apparent relief. An old Quaker hearing of the case, called to see him, and promised to cure him in 24 hours. He gathered a handful of 'life everlasting,' which grows in abundance in every pasture and roadside in the country. A strong tea was made of it, small quantities given from time to time as a drink, and the body freely hathed with it and kept wet. The relief was wonderful, and no one was more surprised than the doctor. In two days the hody of the hoy had recovered its natural proportions, and the fever and itching gone, and recovery fully eetahlished. It is claimed for thie herh that it curee ivy poison so that no return of it is to he dreaded.

Insect Life.—It is eetimated that there are five timee as many kinde of inecte as there are species of all other living thinge put together. The oak alone givee ehelter and support to 450 epecies of iasects, and 200 kiuds make their home in pine treee. In 1849, Alexander Von Humholdt eetimated that the numher of speciee preserved in collcotione was hetween 150,000 and 170,000, but ecientific men now say that there must be sometbing like 750,000 speoies,

SAN FRANCISCO:
Saturday Morning, Nov. 5, 1881

TABLE OF CONTENTS.

MISCELLANEOUS.—Custom Mill Wanted; Bad for Copper Interests of Globe; Cochise District; Important Ruling on Conflicting claims; How to be Dismissed, 293. Precious Metals in the South; Yield of Mines; Magazine District; Hydraulic Mining a State Benefit; Salmon River Mines, 302. Abandoned Mining Districts, 303.

MECHANICAL PROGRESS.—Tests of Constructive Material; Iron and Steel Rolling; Hauling Fires; Compound Steam Engines, 299.

SCIENTIFIC PROGRESS.—The Moon and the Weather; The Influence of Telegraph Wires on Lightning; Meteoric Organisms; Sculpturing with Stone Instruments, 299.

USEFUL INFORMATION.—Wearing Qualities of Aluminum; Underground Telegraph Wires; Fires from Electric Wires; Imitation Amber, 303.

GOOD HEALTH.—Death from a Tarantula Bite; The improvement of Human Life; Wood-Splitting as a Remedy, 303.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board. Notices of Assessments, Meeting and Dividends, 300.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana, Colorado, Utah and New Mexico, 300-301.

ILLUSTRATIONS.—Tustin's Improved Ore Pulverizer, 297. Diagram showing Proposed Levee Building with Slickens, 301.

GENERAL EDITORIALS.—Tustin's Ore Pulverizer; Water Jacket Smelting Furnace; San Luis Obispo Mines, 297. Passing Events; The Hamilton Process; Artesian Well Tubes; New Map of Sinaloa; Mechanic Arts, 300. Levee Building with Slickens; The Debris Injunction, 301.

Business Announcements.

A New Railroad—H. M. Yerington, Supt., Carson, Nev.
Tustin's Rotary Pulverizing Mill—W. I. Tustin, S. F.
Coals—R. W. Theobald, S. F.
Miners Want—New Almaden Mines, near San Jose, Cal.
Foreman Wanted—New Almaden Mines, near San Jose.
Dividend Notice—Standard Con. Mining Co., S. F.

Passing Events.

The miners from the higher mountain camps and from northern mines, are coming now to cities in milder climates to stay the winter out. The season generally has been pretty profitable, and hundreds of new mines have been found all over the country.

The Caesiar mines have shut down for the winter; as a rule, the miners have done better this year than was expected. One Chinese company took out $4,000 in six weeks.

The water company on the Comstock have prepared a large tank to furnish the water requisite to run the hydraulic pumps at the combination shafts with natural pressure. By the making of these arrangements, it would appear that the question was settled and in the near future the pumps would be run without the engines.

The reports that extensive and valuable deposits of petroleum have been discovered in Sweetwater county, Wyoming Territory, appear to be confirmed. A company has been formed under the name of the Rocky Mountain Oil Co., which last year made a number of experimental borings, with very encouraging results. The company at the present time have erected reservoirs capable of storing 1,500 barrels of oil per day.

The disbursements for mining dividends for the month of October amount to $649,833.

THE bullion yield of the Idaho mine, Grass Valley, this State, for the month of October (five weeks), was, in round numbers, $65,000, from which the usual monthly dividend of $7.50 per share, amounting to $23,250, will be paid. This will be the 147th regular monthly dividend paid by the mine, amounting to $3,078,300, out of a gross product of about $6,715,000.

The Hamilton Process.

In a recent issue of the PRESS we took occasion to comment on processes for reducing ores by means of baths of melted lead, giving at the time a brief statement of the various attempts in that direction. These remarks were called forth by the statement that a New York company had been formed for working ores by a process of a lead bath. Since then we have heard of more details, and find that the inventor, Walter Hamilton, proposes to work ores for $1 per ton, a thing which, with all due respect to Mr. Hamilton, we very much doubt his being able to do, as the simple handling looks as if it would cost that much. Of course the new (?) process is to leave nothing in the tailings. No new process ever did—when being experimented with. It is said that orders for 500 machines of capacity varying from 25 to 100 tons per day have been given, dependent, however, on the success of the works now in course of erection. As this process is intended to revolutionize the working of ores, we give a description of it, as taken from one of the Eastern journals, all of which seem to be in ecstacies over the new process. We can, however, most of us, recollect when we used to take a good deal for granted in the process way, but it was when we were all "green" on metallurgical subjects. Any miner can judge, after reading the description, whether it appears likely that ores can be worked for $1 per ton. It may be remarked, too, that the company controlling the process has 100,000 shares, and that the shares are for sale for $1 each:

"The ore to be reduced is first passed through the ordinary Blake crusher, after which it passes between a series of discs, which revolve together with a curious movement, and placed at varying distances above each other. This reduces the most refractory ore to a powder as fine as ordinary flour, in which condition it falls into a channel and is carried along an endless belt, a distance of perhaps 40 ft. Here it is taken up by elevators into the dust chamber and conveyed by a revolving screw shaft into a rotary furnace, constructed of iron and lined with fire-brick, where it is thoroughly heated, the furnace, by means of shafting, being kept continually revolving. Thence it is conveyed to the top part of a vacuum machine, in which it passes through a peculiar and entirely new process, and then passes into a bath of 25 tons of molten lead. From this point it is made to pass between a curious system of plates, whereby the ore is brought into intimate and absolute contact with every part of the lead, which occupies a little over one minute's time. The actual capacity of this portion of the machine is 25 tons, but as the lead becomes impregnated with the precious metals a portion of the base bullion is drawn off, and more lead is supplied by a peculiar automatic arrangement as rapidly as required. Another peculiarity of this part of the process is the fact that after the precious metals are extracted from the lead the latter is run into pigs and used over again, thus saving any waste whatever.

"In working sulphureted ores a peculiarly manufactured gas is run into one portion of the machine and carries off the sulphur, thus leaving it free from that substance when it reaches the bath, and saving the necessity of extracting it afterward. One of the greatest features of the process is, that from the time the ore is placed into the crusher until it leaves the machine a perfect amalgam it is not handled, and hence a great saving in labor is effected. Besides this, after it enters the rotary furnace it is never allowed to cool, and here again comes in a saving of fuel.

"The entire machinery necessary to the perfection of the process is built within a space of 52x30 ft., including the spaces between the furnaces, which are built of brick, and so formed as to be capable of furnishing all the heat required, mechanical devices enabling it to be directed to any point where it is most needed. The works have been built in the most substantial manner on a foundation of seven feet of solid masonry. Their capacity will be at least 100 tons per day, and all the power required to run them is a fifteen-horse-power engine. They are expected to be at once put in active operation. The company invites mining companies to send it samples of their ores in quantities of not less than five tons, so that they may satisfy themselves of the merits of the process."

WHITE PINE AGAIN.—It is reported that in the Eberhardt tunnel, some of the famously rich ore which once astonished everyone, has been found near the North Aurora line. Some of it will assay $20,000 to the ton. No regular body has yet been encountered, but the existence of these bunches is very encouraging, especially as they are met with at a depth of something like 1,000 ft. from the surface. White Pine may, after all, witness another boom.

UP at Silver Reef, Utah, work is being pushed vigorously at all the mines, and surplus ore is rapidly accumulating at the different mills. The outlook is decidedly encouraging for a most prosperous season, and there is every indication of a largely increased output. The improvement noticeable in the quality of the ore as greater depth is attained is not the least gratifying feature.

Artesian Well Tubes.

The principal difficulty in the ordinary mode of sinking and tubing artesian wells is to force the pipe in tubing of uniform size down to any considerable depth, owing to the lateral pressure of the surrounding earth, and the usual result is, at a depth of from 100 to 200 ft., the lateral pressure is so great that the pipe cannot be moved down with all the force available. The only alternative is to put down a smaller pipe inside of the first, and repeat the same as often as the pipe gets stuck fast, and by that mode, if the well should reach a depth of 500 or 600 ft., it would be of little practical value as the diameter of the pipe at the bottom would be so small.

Benjamin Roberts, of Alameda, has obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for an improvement which is designed to overcome this obstacle. By his improved method he makes the well tubing conical and inclined about two or three inches to the 100 ft., with the large end at the bottom, by which means he not only avoids the difficulty of getting the pipe stuck fast and held by the lateral pressure of the surrounding earth, but utilizes the lateral pressure in forcing the pipe down—very little force more than the weight of the pipe and the lateral pressure—where the earth is excavated inside and underneath the pipe.

A well say of 1,000 ft. would be started with pipe 30 inches in diameter, and inclined two inches to the 100 ft. it would terminate at the top with pipe 10 inches diameter, which practically would be equal in value to a well 30 inches in diameter the entire depth, and would cost less; and further, it would be impossible to sink a well 1,000 ft. of 30 inch diameter of uniform size pipe. A well constructed with conical pipe as proposed, would be like receiving the water into the large end of the funnel instead of the small end, as by the old mode.

The boring or excavating of the well for the cement pipe can be done by hand or steam power, and with any of the well-known tools. The inventor prefers sand pumps constructed of half-inch boiler plate, armed on the bottom with heavy barbed irons for picking or loosening the earth or rock, the whole weighing 500 or 600 lbs., and worked by a rope attached to a hoisting engine alternately hoisting and letting it drop eight or ten ft., which would loosen the earth and fill the sand pump with the loosened material. The sand pump would be constantly changed in position, so that it would not strike in the same place, and spring tools would be used to cut away the earth from under the edge of the pipe.

Each inner section extends about half way into the outside section below, and is secured to it. The upper end projects out, so that the next section above slopes over it. The inner pipes all abut, so that the tube is double throughout its whole length, and has the strength of both tubes.

New Map of Sinaloa.

We had an opportunity this week, of examining the drawings for a new and complete map of the State of Sinaloa, Mexico, by Frederick G. Weidner, topographical and mining engineer, who arrived in this city a few days ago from Mexico. It consists of three special maps or sections, viz., a topographical, an ethnographic-linguistical, and a geological one. This latter, the first of the class we have seen of Mexico, shows all the mining districts of that State and adjoining parts of Durango, Sonora and Chihuahua, with their respective topographical and geological formation. The map, when published, will be accompanied by a pamphlet that explains the location of the most celebrated mines, and contains valuable information on general statistics, geology and meteorology. The map is to be issued by subscription, and lists are at the State Mining Bureau, Sutter street, and with the Secretary of the Geographical Society, of this city. Mr. Weidner is at 606 Montgomery street, room 44, and those desirous of any information concerning the northern part of Mexico, will do well to call on him. Mr. Weidner, a graduate of Freiberg, went to Mexico in 1850, and has been living since mostly in the northern States of our sister republic, viz., Nuevo-Leon, Coahuila, Durango and Sinaloa. In all these States he was appointed successively, by the local governments, State Engineer. He has been engaged in surveying and mapping mines, and as he traveled through all that country, brought to light and explored many of the hidden mineral deposits, and other natural resources, and succeeded in making the topographical and geological maps of those States. He is an active member of the Mexican Geographical and Natural History Societies.

IMPORTANT and extensive improvements are now going on at the Parrot smelter, Montana. Its present capacity, with but one reverberatory furnace, is only 12 tons daily; but such is the vast amount of pay ore in the Parrot mine, that it has been decided to increase the smelting capacity of the works. With this end in view, the building of four new reverberatory furnaces is now progressing, which, when completed, will give the smelter a daily capacity of 50 tons.

Mechanic Arts.

The Encouragement of Home Industries.

An attempt is being made in this city to organize a series of lectures for mechanics, on practical subjects, by practical men, and on Thursday evening of last week a number of persons met at Capt. McNevin's Nautical school, corner Beale and Harrison streets, to hear the first lecture. It consisted really of a plain talk by Mr. Irving M. Scott, introductory to the course, explaining the objects, and what was hoped to be accomplished. Mr. Scott's remarks were apt and telling, and were frequently applauded; and we have no doubt many of our readers, unable to be present, will be glad to read what was said:

Every mechanic in San Francisco has felt the need of an organization in which elementary principles can, at least, be taught. We need more friction here. San Francisco ought to get rid of her petty jealousies, and her citizens ought to labor, to some extent, for a common good.

If any one man engaged in the mechanical arts knows more than his neighbor, let us shake hands and get to know him. We will make our bread and butter easier when we know the best method of doing work. I have for years thought that the Mechanics' Institute ought to establish schools and classes. This has been beyond the control of the Institute, however, and they have put off from year to year what now Capt. McNevin comes to the front to do. And I say, all honor to him who labors in such a direction.

In all branches here there are plenty of men to teach—men of ripe experience and judgment. Yet our young mechanics do not have the advantage of our knowledge till it comes out in a book or pamphlet, and these do not come out frequently enough. All over the older countries are lots of institutions where subjects are discussed openly. No man feels above his neighbor there so much as to refuse to share his knowledge. We ought to follow this example here.

We must grow here, and in order to do this must foster every trade. We have here men as eminent in shipbuilding as anywhere, but we lack some facilities. Why encourage ship owners to go abroad to buy ships? All we need in this city is to manufacture the material here. The commerce of San Francisco is in its infancy. It is not so very many years ago that we had to go to Oakland in a whitehall boat. Now great ferry steamers for a few cents carry us there day or night, smoothly and quickly. Our commerce to-day is in the whitehall stage, compared to the future awaiting it.

All down the coast of South America, the islands of the Pacific, Japan, and China, are opportunities for trade with us. We must have dry-docks here equipped and managed, so that the trading vessels will spend their money among our mechanics. We ought to teach our young mechanics what our future is to be. That man is a worthy and good citizen who inaugurates a series of lectures such as we indicate, as it is a step towards the end.

But this is only one branch. As long as food is too plentiful in one country and too scarce in another, so long will engineers be required to assist in equalizing this production and supply.

You may go into the question of mechanic arts, but I tell you that I believe that mining is the only industry that has been loyal to the mechanic arts. All its wants are supplied at home. Agriculture goes abroad for her reapers, mowers, threshers and other implements. All these are imported, so that agriculture has done but little for the mechanic arts here comparatively. That field is almost virgin soil. Some young mechanics will take up these branches and have the money spent with us that now goes away.

The tools used in the mechanic arts can now, some of them, be made here. A tool company has been organized, and this field will soon be fully filled.

I went, the other day, into a linseed oil factory, and found that the farmer who raises the plant, only sells the seed. He does not retain the fiber. Who shall start the factory to utilize that? There is a demand and market for the oil; make one for the fiber, too.

The rope works of this city, which I recently visited, have tools there which would employ a foundry a year to make; but not a pound was made here. Not a pound of the raw material was grown here. The proprietor told me he needed a new and a larger engine. He had had this one 17 years. It was built in Providence, R. I., and had done such good work, that he thought he ought to go back to Providence to get the new one. I told him Providence ought to work up some of that hemp for him if he did.

You all know how slight a proportion of the mechanic arts labor is employed at home. Our boys and girls must find the fields all unoccupied, as we did when we came to this country. They will have to make new fields, and let us help them all we can with our advice and experience, at least.

The average product of man's labor here is greater than in most places, because of the mildness of the climate. I visited the old world not long ago, and I really wish I could convey to you an idea of the advantages you have in California.

In Europe every little wisp of straw is of value, because it has a value, and necessity is

tha spur behind the people, not economy. Some ona makes his living out nf the wisps of straw. If yon untie a package and throw away the paper and string in your room, and afterwards want the string or paper, they will charge you for it. You can be more free in a young country lika this, but Europe has had ita lines of ownership drawn for centuries. You are in a land of plenty. You can lay by for old ages by industry. enough for your purposes. We want to start and develop all the new industries we can, and the first step is to educate the men to carry them on.

During the 22 years in which I have been engagad in the foundry business in this city, every man of industry whom I have known has done well. My apprentices are all at work at one place and another around the country. As soon as they have experience, my neighbors aro always glad to have them, and all these lads are well-to-do. No mechanics of industrious habits are ever out of work.

In England, I went in a stranger to an institution where certain discussions were being carried on. I felt perfectly at home. There were the first engineers of England reading papers on good subjects. Afterwards men got up and discussed the subjects, telling how their experiences led to different conclusions. They were all in friendly communion. The result was, I had the experience of the 20, or 30, or 40 years of work of these men. This is the only case I remember where I got something for nothing.

Not long a man came into my office and said we did not know how to make boilers. He had heard of some new improvements not in use here and told me one of them. I turned to my desk and took up a pamphlet describing the system with all its details. It was an English book and the discovery had already been heralded. Suppose they had bottled up that information and not told us. We could not have had the benefit of their wide experience.

When the big steam yacht *Livadia* was tried every engineer in the United States knew all about her as well as if he had seen her. Knew of the slip of the propeller, speed, coal, whether she rolled or not, etc. Every engineer knew that the steel boilers failed, and why. All this experience we had at the expense of the Czar of Russia.

Why not build up an institution here to exchange views. We must raise our own mechanics here. We used to import them, because there were no young men here.

I do not know much about ships, but I would take a contract to build one, simply because I know a man who can do it. In Baltimore, where I came from, they are very conservative. One follows the other's business. The grandfather, the father and the son will be in the same store, and there is no advance for the son until the grandfather steps out and the father steps to the front. They are too conservative. This city, though it has advantages, never took any lead in mechanic arts. There are no grandfathers here, and each one may move upward independently.

Let us help everyone, and ask him to tell us what he knows.

Did you ever hear of mining stocks? We have been going through an era of depression in mining stocks, and it has been really a godsend to us; but let us have no more kite flying and no more paper. Let us have 40 shops where we now have one. Let us shut out all importation. Let us put our intelligence into lectures and into papers, and let us organize all our industries and forbear speculation.

Every Thursday you will hear in this room a lecture on some subject. You will be privileged to come here, and if the room is not large enough we will get a larger one. See if we cannot organize a true mechanics' institute to help our young mechanics.

When Rome was in her glory the proudest boast of her citizens was that they were Roman citizens, and this fact gave them a fellowship with the leaders of the world. Let us be so true to the mechanic arts that when one comes to the door and says, "I am a mechanic," let him come forward and have any privilege that is held within the gift of the State.

Mr. Richards, of the San Francisco Tool Works was unexpectedly called upon to make some remarks. He said there was not much to be added to what was already so well said by Mr. Scott. He gave some account of what had been accomplished by English institutes and by the Franklin Institute in the East, the only one like those in Europe. He thought this latter institute had contributed mainly to the mechanical progress of the city in which it is situated, and made it what it was. Mr. Richards paid a compliment to the amount of engineering knowledge he found in California, and said it was a most remarkable fact that there was no institute such as this. He promised to prepare a paper before long.

Mr. Dickie, of the Risdon Iron Works, said this was the first revival meeting he had attended for some time; and he noticed that, like all revivals, it began with a praise service. As regards our climate, Mr. Dickie differed from most people in his estimate of its advantages. He thought mechanic arts flourished better in inclement climates. A place with a bad climate will outstrip others with the advantages of position. He instanced Liverpool, with its docks which were born of the necessities of the location; Aberdeen, where the miserable weather and short winter days made them put up big enclosures and buildings. It required dogged perseverance to overcome the difficulties in such places, and this fostered the industries. Mr. Dickie promised to read a paper on "Marine Engineering on the Pacific Coast." In this, his specialty, he hoped to interest the audience. He told those present not to expect too much of these lectures. If the lecturers gave the men a start to set them thinking for themselves, it is all that can be done. If this only is accomplished the lecturers will do great good.

Levee Building with Slickens.

[Written for the PRESS by R. G. SNEATH.]

I had the pleasure of visiting Marysville and vicinity, and many of the hydraulic mines, with the committee lately appointed by our citizens for the purpose of examining into this great question which is now absorbing the attention of the people of the whole State; and although an old resident, and somewhat familiar with the situation, I was surprised at the large amount of damage done the agriculturists in that vicinity.

Much of this damage, especially that on the low bottom lands, cannot fairly be charged to hydraulic mining, as it happened from 1857 to 1862, which was before the Giant was invented, I believe, and when that class of mining was in its infancy, every year, however, has increased the spread of the debris until now, and must increase unless some remedy is applied, even if mining of all kinds should cease altogether, as the mountain streams, gulches and valleys are choking full of gravel, sand and slickens, and must come down to the lower valleys, if not stopped, and for this reason it is well that the farmer should look to the miner to assist in stopping this flow, for the farmer cannot do it unaided.

Much has been said by the newspapers of late concerning the extent of the damage, and very little in relation to any remedy. The papers of the agricultural districts claim that the miners shall stop until they can impound their tailing; and the miners claim that they must continue, in order to get the gold to build the necessary impounding dams.

Both interests are very large, and to kill or cripple either, would result in great injury to the whole State. Mining seems to be in its infancy, and may yet prove to be much the more important industry of the State; and the very farmers, that years ago, as miners, helped to fill the mountain streams with debris that is now coming down upon them, may yet abandon their farms, after wearing them out in the present fashion, say in 15 or 20 years, and return to the mountains in search of gold, as a more profitable employment and a more permanent investment.

Both interests should be protected and harmonized, and the great question is, *how can it be done at an expense that will be justifiable and in time to save further destruction.*

I believe that much of the demoralization of our people on this subject has been caused by the large outlay already without much perceptible benefit, and the statements from prominent sources that it will require at least $5,000,000 the first year and about $1,000,000 annually thereafter to impound the debris and clear the navigable rivers sufficient for navigation. This would be impracticable, as no such sums could be raised.

I will now give you the conclusion I came to after looking over and considering the matter of the remedy:

1. I would throw up stone dams in the canyons of the streams, in the mountains, as near the mines as practicable, holding what debris there is in the beds now, and what may be put in hereafter. This is admitted practicable, and I learn that the majority of the hydraulic mining companies are willing to attend to it at once, if all the lawsuits against them are withdrawn.

2. To empound and utilize the fine sediment, or slickens, say, take the Yuba river as an example, I would build a canal or ditch on both sides of the Yuba, taking out the water and slickens at the foothills about 14 miles above Marysville, and large enough to carry all the water and slickens flowing in that river during the dry season, and with this slickens, and what could be saved in the winter season, I would build large, broad levees along the river on both sides, and around Marysville, so as to protect it from the possibility of any flood, raise the whole town if desired, and then spread it after that, over the red, gravelly, poverty-stricken land near the foothills, and generally designated as sheep pasture, or continue it down to the overflowed lands of the lower valleys.

Before going further, I will cite the Cherokee or Spring Valley hydraulic mines and canal as an illustration. The slickens from this mine is now carried for nearly 40 miles in a canal 500 to 600 ft. wide, and it is receiving the deposit along its line to the extent of building it up rapidly, and delivering the water free from sediment at its terminus. This company has customers also for the slickens at various points on its line. Farmers find that if it is mixed with the adobe soil, that the latter becomes friable, and can then be cultivated at any season of the year; and evidence was furnished from reliable sources that pure slickens has and will produce a fair crop of both wheat and barley, and I saw a good stand of corn and alfalfa growing in slickens 16 inches deep on the bottoms of Bear river.

I have also seen the building of a large addition to the dam of the Oakland Water Works Co., back of San Leandro, upon the same principle as the Cherokee Works—that is, the material from which the dam was built was carried in solution to the point needed, and there deposited by settling. The earth having been thrown into a ditch of water a considerable distance from the dam that it might be transported economically.

Now, if the miners will continue to furnish this slickens free of cost and in large quantities during the dry season, when it may all be utilized, I do not see why all of the levees required on the upper rivers may not be made from it, all the low lands filled in, all the foothill poor lands accessible redeemed, and water for irrigation purposes furnished plentifully at slight cost, and at an elevation sufficient to furnish power, and made applicable by gravitation.

I feel confident that slickens will in turn be made to do all these things, and at a very moderate expense, if commenced on a small scale and allowed to work its way along; and judging from the quantity now in the rivers of the north, there will be an ample supply for all, in time.

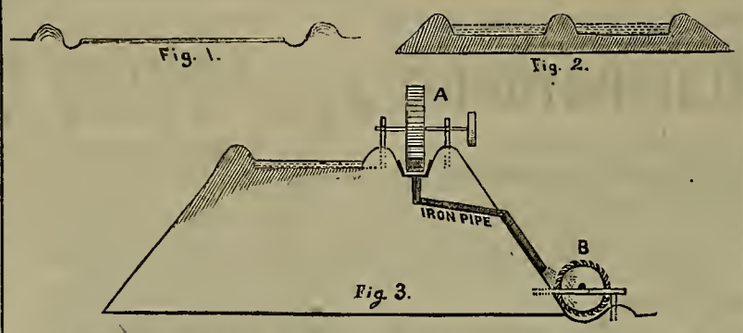

DIAGRAM SHOWING PROPOSED LEVEE BUILDING WITH SLICKENS.

To those not acquainted with the nature of slickens, I will say that it is about half light colored mud, and the other half water; and that on a moderate grade, all the mud will settle on the bottom in a distance traveled of about 40 miles, so that the deposit of the first mile traveled would be much more than the next, and would continue thus until the grade it established increased the velocity of the water and lessened the deposit, so the second mile would in turn receive the larger deposit; and each succeeding mile would thus receive its quota.

Between the foothills and Marysville, the Yuba river and bottom land has been filled with debris, and is now a waste covered with willows to the extent of about ten miles long and two miles wide—in all, say 22 square miles. These willows cause the rapid deposition of the debris, and this space will perhaps hold all that may escape over the miners' dams, or that may not be caught in the side canals, for many years to come; so the remaining difficulty will be to clear the navigable streams below, that navigation will be possible at all seasons, and the channels enlarged, that the floods of winter may have a free outlet. And in this, in the interests of commerce and navigation, I think we can rely on Congressional aid largely, should the people of this State act harmoniously in asking for an appropriation; and I would suggest that, as Congress has done but little in keeping our rivers navigable, that $500,000 annually, for few a years, would not be considered extravagant, considering the situation.

This money I would expend in dredging the rivers and in building broad levees along the principal streams.

Dredging is now done so cheaply that the task will not be so great as many would imagine. Machines are now in operation on this coast that will take the sediment out of the river beds and place it on the banks from 100 to 300 ft distant from the banks, at one cent per cubic yard, and which material is the very best obtainable for levees, and thus forming a wide, solid embankment that would be an ark of safety to those living along the rivers, on which both man and beast might congregate in time of flood.

To dredge along the banks of the Sacramento, say for one mile or 1,760 yards, 5 yards deep and 30 yards wide, would cost $2,640, at the rate of one cent per cubic yard; and it would take about one month's time with one machine. Now, with several machines it would require but a few years to lift the principal portion of the debris out of the streams, and at the same time secure most of the agricultural land from overflow, if not all in time, by the construction of immense levees, and the deepening of the channels.

The owners of the lands reclaimed could well afford to contribute largely toward this work, and the State at large, or that portion especially benefited, should also do their portion and thus all combining a substantial work could be accomplished that would not only save a large territory from destruction, but would reclaim an immense area of land now of no value.

I believe that the value of "slickens" as applied to adobe land, is imperfectly understood, and that when it may come into more general use, that it will be found to be of great value in tempering that vicious soil to the consistency of garden land.

And who can estimate the value to the country of a grand canal on each side of the principal rivers of the State, with an elevation sufficient to irrigate the adjoining lands throughout, and furnish motive power sufficient for the purposes of each and every farm!

In conclusion, I would suggest that the whole debris question should be referred to a committee large enough to represent the several interests fairly, and let them prepare a detailed plan, in connection with competent engineers, that would harmonize the many interests involved, and allow a continued prosperity to all.

Explanation of Diagrams.

The diagrams on this page show the manner in which levees can be built with slickens, and the flow of water used to furnish power for useful purposes and for irrigation.

Fig. 1 shows the beginning of the levee. After the canal has reached moderately sloping land, plow up two ridges, about 100 ft. apart, and confine the slickens and water between them.

Fig. 2 shows the deposit several feet deep. The center division will allow the slickens to be diverted to either side alternately, that the sediment may dry enough to sustain horses and plows, by which the embankments can be raised from the inside from time to time.

Fig. 3 shows the levee and canal completed—say from 15 to 25 ft.—high; the ditch on the right made lower than the canal, to receive its water by crosscuts and from near the surface of the larger canal. After being used as power (on a plain paddle wheel, marked *A* on the top, or on a hurdy-gurdy, like *B* at the bottom), the water can be dropped in the ditch at the base, marked *C*, and conveyed for irrigation where needed. The paddle wheel should be boxed in at its sides, that the full force of the water would apply. The slope of the sides of the levee should be much greater than shown on the diagram, that a sod might be grown thereon.

The Debris Injunction.

On Wednesday, by request of Judge Keyser, Judge H. A. Mayhew, of Tehama, presided in the Superior Court at Marysville, to hear a motion in the case of the City of Marysville vs. the North Bloomfield Gravel Mining Company et al. George Cadwalader and Judge Craddock appeared for the plaintiff; the defendants were not represented. The plaintiff's counsel filed affidavits showing that certain of the defendants had been violating the injunction issued by Judge Keyser, restraining them from suffering debris to flow into the Yuba river or its tributaries. Judge Mayhew, on this showing, made an order requiring the said defendants to appear in the Superior Court at Marysville, on the 25th instant, and show cause why they should not be punished for contempt. The defendants named in the order are the Eureka Lake and Yuba canal company, Boston mining company, the Milton mining company, the China mining company, and the North Bloomfield mining company, all operating in Nevada county. The order commands the Sheriff of Nevada county to proceed forthwith to the mines of the said mining companies of the defendants and close down and shut off the water therefrom, and keep the same closed down and the waters thereof shut off until the further order of the court. In the case of the Eureka Lake and Yuba canal company, the order provides that if R. McMurray, managing agent of said company, cannot be found, sufficient service of order shall consist in posting a copy of the same in a conspicuous place on the mine of the said company, and serving a copy on the attorney for the said defendant. McMurray has hitherto evaded service of the injunction, and is the sole representative in this State of the Eureka Co.

THE White Pine *News* (Cherry Creek, Nev.) says: The railroad survey made within a hundred yards of our town limits, and the heavy grading now being done within four miles of us, and on other points on the line, are the best evidence of the road's speedy completion. When open to traffic it will give us direct communication east and west, and will of course greatly reduce the cost of mining in our district.

T. H. ROONEY, formerly superintendent of the Sierra Nevada mine and Union shaft, has been appointed superintendent of the Utah. A. G. McKenzie, formerly of the Utah, takes Mr. Rooney's place as superintendent of the Sierra Nevada and Union shaft.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

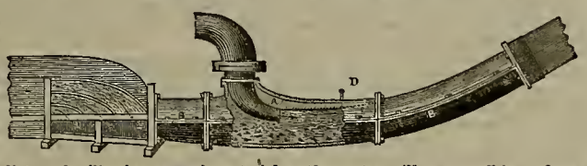
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.



No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY.

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co, S. F.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

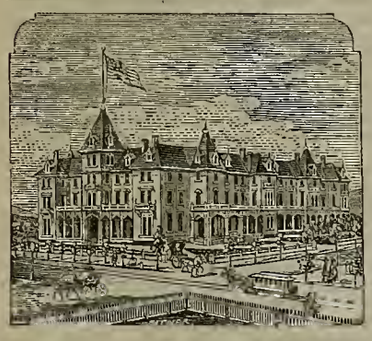
VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Buck Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.



TUBBS HOTEL,

East Oakland,

Having been Thoroughly Refitted and Refurnished, Painted and Frescoed, is now Open for the Reception of Guests. Rooms can now be secured at the Hotel.

S. I. KELLOGG, PROPRIETOR.

ENGINE LATHES IN SECTIONS.

Limit of weight for 25-inch Lathes, 300 pounds. For 17-inch Lathes, 150 pounds.

READY WITHIN 10 DAYS,

1 Planing and Shaping Machine 50x20 inches.
1 25-inch Engine Lathe to turn 12 feet long.
1 15-inch Engine Lathe to turn 30 inches long.
1 36-inch Bracket Drilling Machine.

SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

"FRUE" ORE CONCENTRATORS.

I have on hand and for sale, at LOW PRICES, a number of the above Concentrators, of the latest pattern and in perfect order.

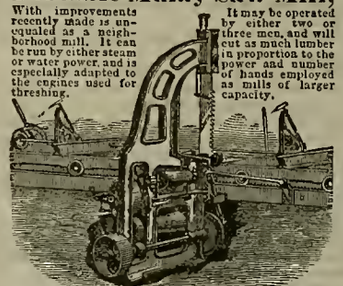
PATENT ADJUSTABLE FIRE GRATE.

It surpasses all other Grates for convenience and economy in use of fuel. No stove complete without one. It will pay for itself in one week. Manufactured by

KEARNS & CALDWELL, 901 Shotwell St., S. F.

Portable Mulay Saw Mill,

With improvements recently made is unequaled as a neighborhood mill. It can be run by either steam or water power, and is especially adapted to the engines used for threshing.



It may be operated by either two or three men, and will cut as much lumber in proportion to the power and number of hands employed as mills of larger capacity.

It makes smooth and even lumber, leaves no stubs bot, and will cut any sized log up to four feet in diameter. It may be transported from one locality to another and re-erected ready for sawing in from two to three days, and can be made profitable in localities where there is not sufficient timber to justify the erection of a large mill. Send for descriptive circular, price, etc., to

CHANDLER & TAYLOR, Indianapolis, Indiana.

We also build the heavy Standard Circular Saw Mill, with either one or two saws as well as the Pony Circular Saw Mill that is capable of being run with light power. We also build Stationary Engines of varied capacity; also, portable Threshing Engines.

TAMALPAIS HOTEL,

SAN RAFAEL.

This well-known and favorite hotel is now open for the reception of guests. Newly furnished. FIRST-CLASS in every respect.

TABLE supplied with the VERY BEST the market affords. The long experience of the proprietor enables him to make the TAMALPAIS the most desirable country house on the coast.

The salubrity of the CLIMATE and beauty of the SCENERY is world-renowned.

W. O. GRAHAM, Proprietor.

REMOVAL NOTICE.

The Sweepstake Plow Company's Works have been removed to

Benicia from San Leandro.

SHEET IRON PIPE.

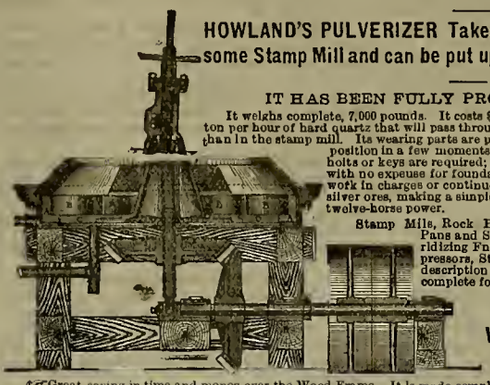
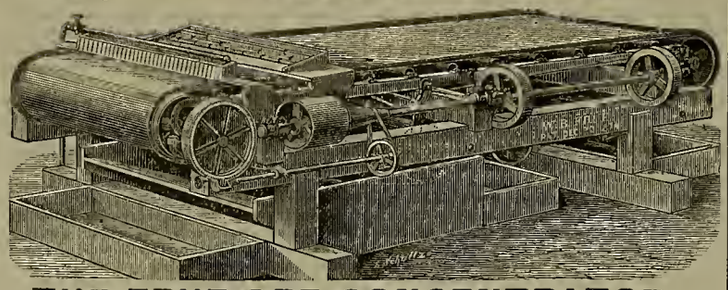
MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery


HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill. It requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

$1,000 CHALLENGE!


THE FRUE ORE CONCENTRATOR.
Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.
We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.
☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.
ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

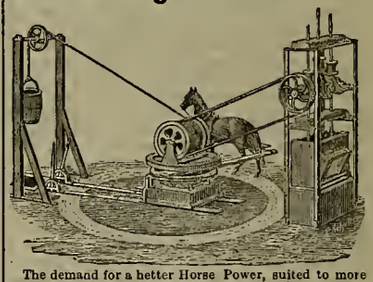
New Mining Horse Power.


The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING OCTOBER 25, 1881.

248,630.—TOILET ARTICLE—Arment & Scott, Dayton, W. T.

248,565.—APPARATUS FOR AMALGAMATING ORES—M. P. Boss, Oakland, Cal.

248,633.—HEADER—Ira H. Bradshaw, San Leandro, Cal.

248,664.—ARTESIAN WELLS—Benj. R. Norton, Alameda, Cal.

248,787.—ROCK DRILLING MACHINE—H. F. Parsons, S. F.

248,605.—ADDING MACHINE—Wm. Perry, Santa Barbara, Cal.

248,791.—QUARTZ MILL—A. E. Redstone, Oakland, Cal.

248,805.—COMBINED BLOWER, LIFTER AND GAS LIGHTER—R. W. Silvey, S. F.

248,653.—DERRICK WAGON—W. H. Worth, Petaluma, Cal.

248,642.—WATER JACKET FOR SMELTING FURNACE—Geo. W. Fogg, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

DERRICK WAGONS.—Wm. H. Worth, Petaluma. No. 248,683. Dated Oct. 25th. This patent relates to that class of agricultural implements known as derrick wagons, and more especially to certain improvements in the means for operating the winding drums or spools, whereby the independent opposite lifting forks are lowered with facility by the operation of a single lever. The invention consists in two drums or spools loosely placed upon a shaft supported appropriately upon the frame of the wagon. The inner ends of these spools are adapted to receive a conical clutch, which is upon a feather on the shaft, between the spools, and which is pushed to either side by a proper lever, and is forced ultimately into the ends of the spools, causing them to revolve by friction. A suitable braking device is provided for stopping the operation of either spool, when necessary.

HEADER.—Ira H. Bradshaw, San Leandro. Dated Oct. 25, 1881. No. 248,633. This invention relates to certain improvements in the construction of headers, and it consists: First, in the employment of iron having an H section peculiarly united to form the frame of the machine; secondly, in a novel construction of the sickle bar, and thirdly, in certain details of construction. It further consists in a novel means for raising and depressing the sickle bar.

THE WESTON ELECTRIC LIGHT.—Exhibitions in this light have been given this week at the factory of the California Electrical Works. The Weston generator is of the celebrated Siemens pattern, modified very successfully by Weston. Where the Brush light requires a full speed, or about 900 revolutions of the armature to produce a light of nominally 2,000 candle power, the same light is said to be produced by from 500 to 600 revolutions in the Weston. The lesser number of revolutions prevents heating and the armature being smaller in diameter necessarily takes less power. The oiling on the commentator of the Weston generator is also reduced to a minimum and offers very little friction and correspondingly small wear and tear. The light was shown with three different styles of globes, opaque, ground all over, half ground and half clear, and with a reflector without a globe. While the light in all was a pleasant one, soft, steady, bright and mellow, that given through the globe of half ground glass seemed to give the most satisfaction. The lower half of the globe is ground, breaking the intensity of the light below, and spreading the full power above and around. It is said that the C. P. R. R. company will adopt this light at the new depot on Oakland pier.

REPORTS to the Navy Department say Commodore Shufeldt is cruising on the coast of China in the yacht of the Viceroy, Li Hung, with two Chinese naval officers, for the purpose of locating naval stations. He hopes to organize an Imperial system of naval administration to take the place of the present barbaric method of governing, equipping and paying the Chinese naval service. Lieutenant Mannix has been made a Mandarin.

THE Visalia *Delta* says: To give an idea of the wheat production in the Mussel Slough section this season, we shall state that one out of the seven firms buying wheat at Hanford has, since the 1st of July last, purchased 7,000 tons of wheat, 4,000 tons of which have been shipped to the bay, and 3,000 tons are still held by this firm. Where is the section of the same area that can beat this?

THE question of the independence of Canada is being discussed in the Dominion.

What They Say About the Comstock in New York.

[From our Regular Correspondent.]

EDITORS PRESS:—To show you that the state of the speculative market influences the judgment of stock operators as to the merit of the mines just as completely here as in San Francisco, I quote the following paragraph from the New York *Evening Post* of the 24th inst., which may be taken as expressing the average public sentiment at the present time:

"The San Francisco market for mining shares has shown weakness and a steady decline this last few days, especially in the northern Comstocks, where the alleged new bonanza exists. Every artifice known to stock manipulators has been tried to tone up the market; all have failed. The upper part of the lode has been pretty thoroughly worked out and no profitable ores now exist above the heated levels. It may be that vast ore bodies might be found below the present works if it were possible to go deeper. But with the thermometer at 160°, and the heat rapidly increasing at every foot of depth gained, there is little prospect of finding them in this generation. In portions of the California and Con. Virginia mines the heat caused an entire stoppage of work some weeks since, but by means of fans and blowers sufficient air has been introduced to allow a resumption of operations. The Bank of California is gradually withdrawing from all connection with mining operations."

Only a few weeks ago, when the incipient and disappointing Sierra Nevada boom was making itself felt here, the tone of the press and of the general public was altogether different. Highly exaggerated accounts of strikes in the north-end mines of the Comstock lode were current and were as a rule believed. Now, without any definite or reliable information as to the true existing state of affairs in these mines, and guided solely by the indications of the San Francisco market, people here are just as despondent as to the future as they were over-sanguine when the market was rising.

All this goes to prove what I affirmed in a former communication—that New Yorkers are undergoing precisely the same experience with regard to mining, from the speculative point of view, that has been passed through by the "outsiders" of the Pacific coast. It is to be hoped that the lesson will be learned at less expense.

Last week the aggregate transactions reported at the two local mining exchanges amounted to $12,013 shares, a large proportion being of very low-priced stocks, and probably much of the quasi business being wash sales. The figures quoted mark a considerable decline from the preceding week's.

The transfer of bullion to this city for sale and for refining is considerable, amounting to from $250,000 to $300,000 per week. This is a significant index of the growth of the legitimate mining business, taken as a whole, in New York, notwithstanding the many setbacks which have occurred and the prevalence of wildcat schemes. PAUL WARD.

New York, October 26, 1881.

TO WORK AURIFEROUS CEMENT GRAVEL.—The Barrett Bros., at Peoria Bar, have invented a cement grinder to work their ground in Table mountain, at that point. It consists of an upright column, on which are attached five or six loose-jointed arms, on the end of which are attached 4-lb. hammers, which make 300 revolutions per minute. The whole is encircled in a casing similar to an arastra, and on the inside rim are wedge-shaped pieces of iron at intervals, for the iron fists to strike against in their rapid revolution, which grinds the cement equal to any quartz mill. They claim to save 80% of the precious metal, and after some intended improvements, the proprietors are prepared to put it against any mill in the country for this kind of mining.—*Tuolumne Independent.*

DISPUTED OWNERSHIP.—The work in Yellow Jacket ground at "Prospect drift, at point 4,035 south lateral" of the Sutro tunnel, is carried on by the tunnel company, as they claim the ledge discovered there. The Yellow Jacket folks likewise claim the ledge, holding that as they paid the tunnel company for running the south lateral branch through their ground, and as it is outside of the charter granted the tunnel company the latter have no claim upon it. The question of ownership will be quickly tested in court by the Yellow Jacket company, should pay ore be found. As it stands now, they do not care to contest the matter, as they claim they are getting a knowledge of the resources of their mine in that direction without paying therefor.

WE see, by the Bedrock *Democrat* (Oregon), that Washington district, on Snake river, is now coming into prominence. Several lodes of great value have recently been discovered there. There are copper, iron, gold, and silver carbonates. The principal lodes discovered have been located by Henry Martin, Hoffman & Co. They are the Daniel Boone, Henry Clay, Wide West, Atlanta and Bonanza.

C. C. BEAN is busily engaged in putting up a smelter for the reduction of copper ores in Copper Basin, Arizona. Inside of 60 days he expects to have his furnaces in operation and producing 2,000 lbs. of copper matte per day.

News in Brief.

THE rainfall for October was .54 of an inch.

CALVIN BROWN, civil engineer of the stone dock at Mare island, has been retired.

RAILROAD talk is agitating Winters. The people hope for an extension of the line to Lake county.

THE winnings of the American horses in England and France this year amount to about £30,000.

THE formal transfer of the North Pacific Coast railroad to its new owners took place on Monday last.

ICE from Lake Ladoga has flowed into the river Neva, Russia. Steamboat service has been suspended, and all the canals are frozen.

IT is rumored that parties have leased the Watsonville beach, and propose expending $15,000 in converting the same into a seaside and bathing resort.

BANK COMMISSIONER COLEMAN examined the Modesto bank, at Modesto, on Wednesday last, and found it solvent. The liabilities and assets are $495,535 88.

TWENTY deep water vessels arrived in this port one day this week. There are 148 deep water vessels now in harbor. They are loading at the rate of two each day.

THE taxable property of Esmeralda county, Nev., as shown by the assessment roll, amounts to $1,214,626.98. The tax this year foots up $35,831.51.

THIS will be the greatest year of railroad building in the history of this country. The year 1872 was a wonderful one in this respect, having witnessed the laying of 5,147 miles of track, but to the present time in 1881, with 2 months still remaining, 5,340 miles have been laid.

GEN. DRUM, in his annual report to the general of the army, says: The losses of the army during the year were: Deaths, 248; discharges, 6,564; desertions, 2,361. Total, 9,173. Number of recruits assigned, 3,805. This shows an increase of 1,260 discharges, 13 deaths and 318 desertions.

A STATION is to be established at the Volcano House, on Kilauea, which will be in communication with the United States Metsorological Department, and next year a proper record is to be kept of the movements of the volcano, and a series of observations of volcanic phenomena will be undertaken.

FOR some time past it has been whispered that the English government intends to sell Gibraltar to Spain, and the story seems to have some foundation. It is said that the subject has been discussed in the Cabinet and that the Premier's proposal met with no very decided opposition from the colleagues.

THE final location of the Northern Pacific has been made from the north side of Lake Pend d'Oreille to a point 40 miles above the mouth of the river. The preliminary lines run to Thompson's river, 100 miles west of the Missoula. There is considerable snow now, but a large force will be kept at work all winter.

STOREKEEPERS are generally displaying notices calling attention to the value placed on mutilated coin by the Treasury Department, and stating that no mutilated silver will be received, except upon the basis of value fixed by the Secretary of the Treasury, as follows: One dollar, 65 cents; half dollars, 35 cents; quarters, 15 cents; dime, 5 cents; half dime, 4 cents.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies, postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 252 Market St., San Francisco, Cal.

OUR COMPLIMENTS are due Heald & Banks, machinists and model makers, No. 514 Commercial street, for the substantial manner in which they have made fast our sign in a difficult position.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

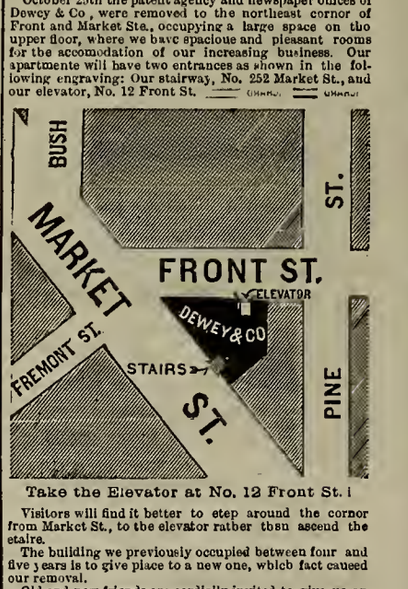
NELSON GOROM, Serg't Signal Corps, U. S. A.

Business and Patent Office Removal.

October 20th the patent agency and newspaper offices of Dewey & Co., were removed to the northeast cornor of Front and Market Sts., occupying a large space on the upper floor, where we have spacious and pleasant rooms for the accomodation of our increasing business. Our apartments will have two entrances as shown in the following engraving: Our stairway, No. 252 Market St., and our elevator, No. 12 Front St.



Take the Elevator at No. 12 Front St.

Visitors will find it better to step around the cornor from Market St., to the elevator rather than ascend the stairs.

The building we previously occupied between four and five years is to give place to a new one, which fact caused our removal.

Old and new friends are cordially invited to give us an early call in our new quarters.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARND C. HOAG—California.
B. W. CROWELL—Yuba and Sutter counties.
D. W. KELLEHER—San Mateo and Santa Clara counties.
C. E. WETMORE—Alameda county.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

ST. DAVID'S,

A FIRST-CLASS LODGING HOUSE

CONTAINS 113 ROOMS.

715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 8 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from $2.50 upwards

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company,

SAN FRANCISCO, CAL., NOVEMBER 2, 1881.

At a meeting of the Board of Directors of the above named Company, held this day, dividend No. 34, of seventy-five cents (75 cents) per share was declared, payable on Saturday, November 12, 1881, at the office in this city, or at the The Farmers' Loan and Trust Company in New York. WM. WILLIS, Sec'y,

Office—Room No. 29, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

Newcastle Gold Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Yaokee Hill Mining District, Placer County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Twenty-third (23) day of September, 1881, an assessment, (No. 21) of two (2) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 33, No. 318 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the First (1) day of November, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Twenty-first (21) day of November, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

E. G. MATHEWS, Sec'y,

Office—Room 33, No. 318 Pine St. San Francisco, Cal.

POSTPONEMENT.—The day of delinquency of the above assessment is hereby postponed to the fifteenth day (15) of November, 1881, and the day of sale to Monday the fifth day (5) of December, 1881. By order of the Board of Directors, November 2, 1881.

E. G. MATHEWS, Sec'y.

Franklin Gravel Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dutch Flat, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Fourteenth (14) day of October, 1881, an assessment, (No. 7) of Thirty (30) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 310 Pine street, Room No. 44, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fourteenth (14) day of November, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Fifth (5) day of December, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors.

GEO. R. SPINNEY, Sec'y.

Office—No. 310 Pine St., Room No. 44, San Francisco, California.

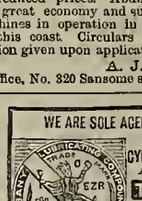
PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

QUICKSILVER.
THE CELEBRATED **A** BRAND, SHIPPED
DIRECT FROM THE
NEW ALMADEN MINE,
For sale in any quantity by the producers. Car Load Lots will be shipped from San Jose for Nevada, Arizona and the East, or delivered at Pacific Mail Steamship Company's Wharf, San Francisco, without charge.
THE QUICKSILVER MINING COMPANY,
J. B. RANDOL, Manager,
No. 320 Sansome Street.
San Francisco.

San Francisco Pioneer Screen Works
J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

Diamond Drill Co.
The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.
A. J. SEVERANCE & CO.
Office, No. 320 Sansome street, Room 58.



RICHARD C. REMMEY, Agent,
Philadelphia Chemical Stoneware Manufactory,
1100 E Cumberland St., Philadelphia, Pa.
Manufacturer of all kinds of Chemical Stone Ware for Manufacturing Chemists. Also, Chemical Bricks for Glove Towers.

PACIFIC MACHINERY DEPOT.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

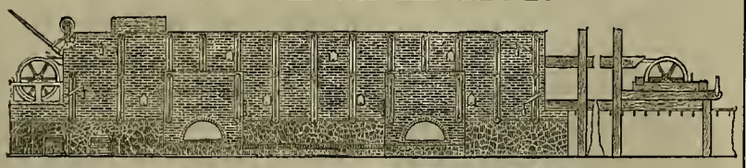
Hoisting and Pumping Machinery.

THE O'HARRA
CHLORIDIZING FURNACE.

Patented in 1878.



SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

—o—

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61¼.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenual sulphurate of silver up to from 84% to 95% of the assay.

VOLUME XLIII Number 20

Weighing Ores.

In England, they used to pay the men by measure for getting out the coal, but now, in accordance with the Mines Regulation Act, they pay by weight. On this coast work is done by the day, without reference to the amount of ore extracted, which of course is necessary in precious metal mining; and in none of our mines are we very accurate in our system of weighing, even where work such as mill work, is done by the ton. Since the introduction of the weight system in England, several devices have been perfected especially for weighing ore. Messrs. Pooley & Sons, of Manchester, have just put into operation at the Pendleton pits some "pit-hauk weigbing machines," on an entirely new principle.

As the machines referred to are the first of the kind which have yet been actually put down, a few details as to their construction will be of interest. The machines are so arranged that the use of weights, springs, racks, pinions and wheels, is entirely dispensed with, the principle upon which they are worked being the creation of a vacuum in a column of water. This is effected by a simple arrangement. An ordinary steelyard is, at the poise end, connected with what may be described as a piston contained in a column of water enclosed within a small tin can, and this takes the place of the usual poise weights. The pressure brought upon the short arm of the lever as the colliery tubs are passed over the weighing table, causes the piston to be lifted through the column of water, and the weight passing over the table is instantly recorded by a moving figure on a quadrant dial, in proportion to the amount of water displaced. A taring arrangement is also provided for allowing for the weight of the tubs, so that the record given on the dial is the exact weight of the contents of the tubs. The action of the apparatus is remarkably quick, six weighs per minute being readily taken over each machine; and Messrs. Pooley, who have applied the same principle to railway wagon weighing machines, claim that a whole train while in transit over the tables, can be easily weighed without stopping. In connection with the pit-hank machines, another feature is the distance at which the weighing table can be placed from the weighing-room; this is the cause of one of the machines at Messrs. Knowles' collieries being 73 ft. The simplicity of the working parts removes to a great extent, any liability to disarrangement in the machine, the danger most apparent in this direction being the possible action of the weather, either by evaporation or frost upon the water column; but this is reduced to a minimum by protecting the apparatus under cover in the weighman's office. So far as these machines have been tried, *Iron* is informed by the colliery officers that they have given satisfaction.

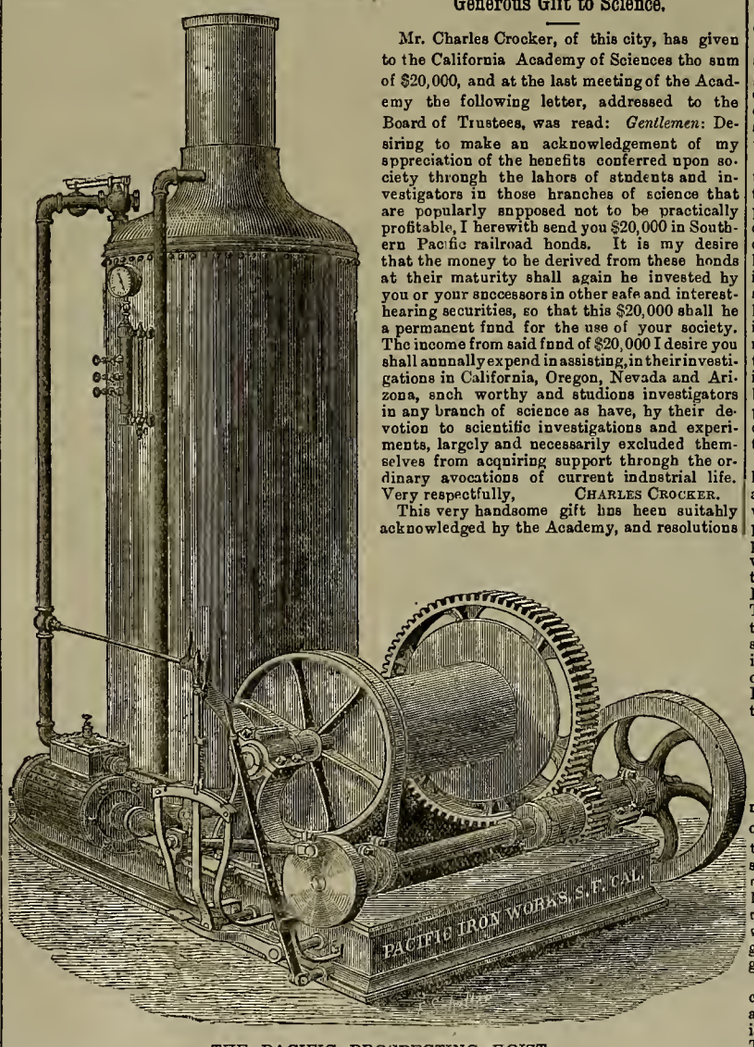
MECHANICAL LECTURES.—A course of mechanical lectures is being delivered at Capt. McNevin's Nautical School, 404 Beale street, corner of Harrison. Mr. Irving Scott delivered the first, which we reported in full. Mr. Wheeler's lecture, of last week, we were unable to give. On Thursday, of this week, Mr. Richards, of the San Francisco Tool Co., delivered a lecture, a report of which we will give in our next. Mr. Dickie, of the Risdon Iron Works, will speak next week on "Marine Engineering." Robt. Moore, W. R. Smedberg, Mr. Eckert, and others, will follow. The lectures are mainly attended by those interested in mechanical pursuits.

A GREAT deal of interesting matter is crowded out of this number of the PRESS to make room for the report of the Debris Committee. For this reason we omit our usual illustration on the 9th page.

THE Virginia company, Tombstone, will now have to build a mill, as they have depended on having their ores crushed at the Boston mill, and the owners of that have now bought a mine of their own which will keep the mill busy.

A New Mining Hoist.

To meet the wants of many mining properties in the early stages of development, Rankin, Brayton & Co., of the Pacific Iron Works in this city, are building the very complete, portable hoist shown on this page. They are made with a single reel attached to the shaft by a clutch, and fitted with a friction brake so that the reel can be lowered with the engine stopped. The engine is fitted with a link motion, so it may be worked for both hoisting and lowering if desired. There is also attached a pump for feeding the boiler.



THE PACIFIC PROSPECTING HOIST.

The hoist is geared about six to one, and the gearing and all other parts subjected to strain are extra heavy. Material and workmanship are first-class in every respect. The reversing brake, clutch lever and throttle, are all placed so as to be conveniently handled by the engineer when at his post. The boiler is of ample capacity, and rests upon a cast-iron base, to which the engine is also attached. The fire box and tubes are made extra large to allow of burning wood in places where coal is not readily obtained.

A large proportion of this class of hoists made at the East, it is well known, are light and flimsy in construction, unsafe, inconvenient, and only answer a very temporary purpose. This hoist is an honest and well-made machine, perfect in all its appointments, and equal to all the demands that may be made upon it within the limit of its capacity. It is confidently presented by the manufacturers as the most convenient small hoist that has ever been gotten up for mining purposes.

The general dimensions are as follows: Engine cylinder, 6 in. x 8 in.; boiler, 34 in. diam. x 7 ft.; drum, 12 in. diam. x 26 in; flanges, 24 in. diam. Drum carries 600 ft. 1¼ in. diam. Manilla rope. Will work to a depth of 400 ft. with a load of from 1,800 to 2,000 lbs.

Generous Gift to Science.

Mr. Charles Crocker, of this city, has given to the California Academy of Sciences the sum of $20,000, and at the last meeting of the Academy the following letter, addressed to the Board of Trustees, was read: *Gentlemen*: Desiring to make an acknowledgement of my appreciation of the benefits conferred upon society through the labors of students and investigators in those branches of science that are popularly supposed not to be practically profitable, I herewith send you $20,000 in Southern Pacific railroad bonds. It is my desire that the money to be derived from these bonds at their maturity shall again be invested by you or your successors in other safe and interest-bearing securities, so that this $20,000 shall be a permanent fund for the use of your society. The income from said fund of $20,000 I desire you shall annually expend in assisting, in their investigations in California, Oregon, Nevada and Arizona, such worthy and studious investigators in any branch of science as have, by their devotion to scientific investigations and experiments, largely and necessarily excluded themselves from acquiring support through the ordinary avocations of current industrial life. Very respectfully, CHARLES CROCKER.

This very handsome gift has been suitably acknowledged by the Academy, and resolutions adopted that the endowment be known as the Crocker Scientific Investigation Fund.

Mr. Crocker's gift is well bestowed. The Academy has struggled along in poverty for a long time, doing its work as best it may. Mr. Crocker has set an example that might well be followed by other of our millionaires in bestowing some of his wealth in a direction where the general public will be benefited. This money will, by the terms of the gift, be a source of continual usefulness, not only in its results, but to the persons producing the results, a class of people which the world is more apt to push aside than to help. All honor, then say we, to Mr. Crocker for his timely and generous gift.

THE Wood River Smelting Works were attached recently, but have resumed work again.

"Grubstaking."

On page 318 is printed a decision by a Colorado judge, which bears on the practice of "grubstaking," so long in vogue in the mining regions of this coast. We see in several of our exchanges, that the decision is interpreted somewhat differently from what we do, after reading it carefully. The court does *not* hold that people who outfit prospectors cannot enforce their contracts to sever whatever interests may accrue, from the results of the prospector's trip. The gist of the decision is, when a person outfits a prospector and the latter squanders what he has received, and enters into another similar contract with other parties, the first grubstaker cannot come in and enforce any claim on what may be discovered under the second contract and by the aid of the second grubstaker. All the rights are with the person in whose immediate employ the prospecter is.

Most people imagine this to be a death blow to grubstaking, but it simply seems to express the status of the practice, and does not, it appears to us, add any new features. A great deal is left to the honesty of the prospector of course; but a great deal always had to be left to his honesty. He might find a rich claim, leave it and afterwards return to it and take possession; or he might repudiate all claims as has been done hundreds of times. There is no hint in the decision, that grubstaking contracts will not be enforced. There is not even any limitation upon them. The decision simply says that in order for such a contract to be good it must be the one which is actually sustaining the prospector at the time, and pushes to one side all contracts which he may have made previous to the one under which he is in fact operating.

The whole story is, A outfits a man, and sends him to Hailey, Wood River (or anywhere else), and when he gets there, some Hailey man, who we will call B, chooses to also employ the prospector to prospect for him, and if the prospector finds anything, then B who gave him $10 worth of bacon, beans, flour and whiskey, takes the claim, and A who paid his fare to Wood River (or anywhere else), is left out in the cold. This is the plain English of it. According to this, men in mining camps where there are stores, are much more likely to have interests in claims, even than those men in cities who outfit prospectors or the "grubstake" system. It is just as well for people to remember what the law on the subject is.

A Conference of Miners and Farmers.

The Committee of the Board of Trade have not given us much that is new in their report on the debris question, which we publish in this number of the PRESS. The principal result is the appointment of a joint meeting of miners and agriculturists in this city on the 17th, to discuss the question. The conclusions reached by the board are not very marked; but we could hardly expect people in trade to suggest any remedy for an evil which requires engineering knowledge to overcome.

The farmers have evidently impressed the committee greatly, and given the idea that the area damaged is much greater than it actually is. The language of the report shows this. The suggestion that the miners pay all expenses for dams will be hailed with delight by the farmers. But a compromise which throws the burden all on one pair of shoulders is hardly the sort of compromise to meet with general favor.

While the committee have not accomplished more than could have been expected, their mission has served to call attention more carefully to the matter; and has perhaps brought about a feeling that maybe the difficulty can be settled without the aid of the lawyers who are waiting for fat fees from the opposing factions.

We shall await with interest the result of the conference to be held here this month.

THE pocket mines of Sierra county turn out a great deal more gold than most persons suppose.

Salmon River.

The Idaho *Messenger* says: Almost everybody seems to hs laboring under the mistaken idea that not only all this region, hut the Yankse Fork country, and some even think that the rich Bay-horse fislds, helong to Wood River, while the truth is, that all these grand mountains of untold newly discovered treasures lie on the Salmon river waters—and the half, doubtless, is not yet told. Salmon has one side of this wondeful chain of mountains, while it takes Lost river, Wood river, Boise, Payette and Weissr rivers to cover ths opposits side of the rangs, and ws say time will prove Salmon river equal in mineral wealth to all the others combined. We shall no: cry if it does. God made it and we will abide it. But our readers will hear in mind. that not a single ledge we have yet described in the 21 numhers of the *Messenger* lies on any hut the Salmon waters.

Smiley Gulch.

Informatiou had heen given us that all the Lake, Bcaver and Smiley creek cluster of mines lie in granite; and that there was no other formation; but, on entering the Smiley valley helow the town of Vienna, we see a lime reef, which evidently extends into the main range. Snow on the ground prevented us, however, from making a critical examination and the limit or extent of this formation we could not speak of. This may, perhaps, chauge somewhat the uniformity of grades and kinds of ores. At least it will be of great nse for building purposes; and as there ie a town of great promise being built here, lime has its value.

Ae we ascended the mountain divide at the head of Smiley, snow fell in hlinding quantities, and it was with great difficnlty one could find a camp. At last, however, we found the

Vienna Mine

On which the company have run a 200 foot tunnel, cutting the vein at right angles; thence on the ledge they have run ahout 200 feet more. Besides this they have run a second tunnel in about 180 feet; and a third of considerable leugth. The ownere of thie mine are largely interested in the Mountain King, and it is contemplated tbat they will construct a mill for these mines next season. The uppsr tunnels of the Vienna are said to be in very excellent ore.

The Solace.

This mine was discovered last epring and sold thie fall to Haggiu & Co., for the reported sum of $40,000, and ie to have a mill constructed on it in 1882. The vein is exposed hut in oue place of ahout 30 ft. in length and 8 ft. in width, and perhaps, for 6 or 8 ft. in depth. But there it stauds—a grand little mountain of ore, said to sample from $400 to $500 dollars for its whole length and breadth, and to he as whole and compact, almost as that much bulk of cast iron.

The Mountain King

Was rightly named. It is located on the east side of Smiley creek nearly opposite the Vienna, which will he worked with it.

There is a tunnel of ahout 50 ft., perhaps 75, in on this mine starting near the discovery rock and running on the vein. The excellence of this mine is the great capacity or volume of it and the richness of ores with which it is filled.

Besides the tunnel there ie a cut across the mine 100 ft. or more below, where the company are constructing living departments and a shop for repairs as well ae a roof over what will be the working tunnel of the mine. In this cut the vein ehowe a width of full 16 ft, which is merely surface.

There was considerable ore on the dump, all looking rich wherever we tried it, of rnhy and black snlphnretic silver. In this clnster of mines (Smiley's gulch) tbere are native eilver ores, but little, if any, horn silver or chlorides.

Peabody Mine.—The new pumping and hoisting works on the Peahody mine have reached so near completion that the work of pumping out the shaft wae commenced recently. It was but a few weeke ago that the company determined to replace the old worke hy those of more etrength aud capacity, and acting npon that determination, with Robert Cryer as superintendent, and Joseph Slack as master mechanic, the new improvemente have heen carried forward with energy. The new works, as were the old, are to be rnn hy water power, the watar, 100 inches, heing obtained through the V flume. The flume conveying the water to the works has heen raised 11 ft., to he adapted to the new wheel, which ie 36 ft. in diameter, and superior in its construction for etrength and good workmanship. The framework of the building is also very strong, and the storiee are made high in order to provide for a convenient dump. All parts of the machinery for pumping and hoisting have heen made strong, and well adapted to the purpose of opening the mine. The shaft is down nearly 200 ft., and will he pumped ont in a few days, when sinking will he resumed, and at the same time, a drift is to he started, from which ore will be extracted. With the new improvements, the Peahody will be systematically opened, in the expectation that it will prove a good mine.—*Grass Valley Union.*

Eureka.—Attracted hy late developments, the town is filling np with mining men, and many important sales of mining property are under negotiatione. The people of Eureka are confidently expecting a great hoom in the near future.

Eureka Con.

The Secretary's annual rsport of the Eureka Consolidated mine, Eureka, Nsvada, makes the following showing:

From 5,396 tons base bullion	$1,720,313
Sales of Candles	1,260
Sales of Powder, Fuse and Caps	3,384
Sale of boiler	500
Sales of Lumher, Hardware, etc	99
Discount on Coal Receipts	444
Assaying	3
Total receipts 1880-81	$1,726,003
Superintendent's drafts	19,902
Cash in hands Supt. Oct. 9, 1880	97
Cash on hand Oct. 9, 1880	24,521
Total resources	$1,770,523

The dishursements for the past fiscal year have hesn as follows:

Mine account	$ 345,091
Ore account, purchase of 3,069 tons	117,204
Smelting account	435,233
General expense at mine	26,336
Expenses at San Francisco	11,205
Construction new shaft	164,956
Transportation and refining charges	198,620
Twelve dividends	300,000
Legal expenses	9,143
Interest	25
Drafts carried over from last year	1,922
Bill for supplies carried from last year	851
Balance advances Oct. 9, 1880	14,982
Total dishursements	$1,625,966
Cash in hands Supt. Oct. 9, 1881	222
Cash with Laidlaw & Co.	2,000
Cash in Bank of California	142,365
Total	$1,770,523

It ie not out of place to give a brief review of this wonderful mine. The company was organized about a dozen years ago with a nominal capital of $5,000,000, in 50,000 shares. The only actual capital paid up was $100,000 in two assessments of $50,000 each. With this small outlay an immense business has been developed, expensive litigation conducted and large profits dishursed to stockholders. There have heen 72 dividends declared, ranging from 30 csnts to $3 per share. There were no dividende in 1872 or 1876, and there will probably he none for the next six months, or until the present improvements at the miue are completed and paid for. The surplus, $144,857, will harely do this. Beeides the "dead work" and prospecting at the mine will also ahsorh a large dishursement. During the past fiscal year the mine has paid 12 dividends of 50 cente each, making a total of $300,000. The 72 dividends declared were as follows:

	No.	Amount.
1871	6	$ 275,000
1873	4	200,000
1874	4	175,000
1875	8	300,000
1877	4	600,000
1878	12	1,800,000
1879	12	825,000
1880	12	230,000
1881	10	250,000
Totals	72	$4,705,000

Mining in Lake Superior.—The following extract in regard to the "hoss" mine of the Lake Superior country, will he read with interest by our mining men, as giving some idea of the method of working in that region: "The Calnmet and Hecla mine, of Lake Superior, has eight sbafts, the deepest of which is 2,500 ft., deep, while the average of the eight is about 2,000 ft. From each of these shafts, at a distance of 75 ft., run two levels to the extremities, say, each of them three-eighths of a mile long. The total length of drifts would thus amount to about 25 miles. To keep these workings safe, hetween 3,000,000 and 4,000,000 logs are used every year. The ore is boisted to the enrface partly hy the old engine, hut chiefly hy the new compouud engine of 5,500 horse power, with one cylinder 70-inch, and the other 40-inch diameter. The Calnmet and Hecla engine can hoist, and the mine can produce, 1,500 tons a day, but the rule ie that the production ehall not exceed 1,000 tons. On reaching the surface, the ore is loaded in care and hauled hy locomotives over the company's road to the etamp mill, four miles distant, where it is crushed for the smelter."

Good Hope District. —The *Times-Review* has the following relative to Good Hope district, which is eitnated near a fork of the Owyhee river, on the Winnemucca and Cornucopia road: "On the Ohio Con., four men are at work taking out ore. The vein averagee 20 inches, and thc average assay is $98. There is now 120 tons of ore on the dump. Burr Gordon and John Dearden have renewed their lease on the Snyder mine, and have gone to work. It is reported that the ledge in the Silver Brick tunnel has heen struck, and that good ore is bsing taken out.

Beginning on Monday, the "limited express" train will commence runuing over the Fort Wayne and Pennsylvania railroad hetween Chicago and New York. The train, it is claimed, will make the journey from Chicago to New York in 25½ hours, and shorten the actual running time between New York and San Francisco to 5 days and 23 hours.

The Sonth Yuha mining tunnel company'e property, consisting of placer claims and water and tunnel rights on the Sonth Yuba river, in Bridgeport township, Nevada county, has been sold to Geo. T. Emery, of San Francisco, for $12,000.

The Board of Regents of the State University has decided to establish examinations in Los Angeles and Marysville next Jnne, to be held on the same date as those at Berkeley.

The Eureka Tunnel.

A *Sentinel* reporter visited the tnnnel on Friday in company with Supsrintendent Butlsr, and found that work was actively progressing on the ore body recsntly discoversd. The ore was sncountered 1,100 ft. from the mouth of the tunnel. A drift was started almost due sonth on a small vein, not more than 3 in. thick and 4 ft. in width. This streak assayed very high and provsd to be very rich. For the first 10 ft. it continued about the same, when it pinched out almost entirely for 3 ft., leaving only a very small, yellow line, but easily traceable. Maurice Hartnett, the foreman, without being the least discouraged, pnshed the drift ahead, and in the next few feet came against what has since proved to he a solid hody of very high-grade ore, richer in proportion to the quantity than any heretofore taken out in the camp. On Friday, at the time of the reporter's visit, the drift had penetrated the ore a distance of 40 ft., the sides, roof and wall 15 ft. from the tnnnel showing the same rich character of rock. Thirty feet from the tunnel a large incline winze has hsen sunk towards the west to a depth of 26 ft. in eolid ore, the face of the winze showing even better material than that passed through, a heavy vein of hlack metal appearing very prominent. Work on the winze was temporarily suspended, there heing no way of getting out the ore. A etation is, however, heing huilt for a wiudlass. An upraise in the ore, to the east of the face of the drift, was etarted on Friday, in order to test the range of tbe bonanza in that direction. The drift will also be continued south. From the time the ore hody was encountered, the foreman informed the reporter, not a single car-load of waete has heen taken out. A track has beeu laid directly to the winze, and one man handlee a car going and coming without difficnlty, making the extraction of the ore cheaper, probably, than that of any miue on the coast. The atmosphere is cool and pleasant, and hut little inconvenience is experienced from the heavy blasts. The ore and snrroundings are perfectly dry, and water will not trouhle the miners. The extent of the ore body cannot, of course, yet be determined, hut the explorations so far made demonstrate that it must he of vast extent. Seven men are now employed, but this force will be increased as soon as room can he made for them to work comfortably and profitably. All tbe work so far done appeare to exhihit good judgment, and not a dollar has heen wasted. With the present force, Superintendent Butler says, 20 tons of ore can de extracted every day when the windlsss is in shape.

The magnitude of the work and the patience, perseverance and outlay of the projectors can hardly be gleaned from the ahove illustration. The community in general owes a debt of gratitude to Gen. Connor for its incipiency and success. He located it and organized a company. A certain amount of stock was to be used as a working capital, and an effort was made to enlist the public in the enterprise. However, few shares of the etock were sold in thie way, some at 50 cents and some as low as 25 cents; until within the last two years it could not be sold at any price. The gencral public had no faith in the tunnel project, and sent its money to develop the Comstock. The General then determined to carry on the work at his own risk, and has heen doing so up to the time of the strike. He will now receive the reward of his faith and judgment. But in giving Gen. Connor credit for hie share in the enterprise, we must not forget two of his associatee in adversity, E. J. Butler, the Secretary and Superintendent, and Maurice Hartnett, the foreman, hoth of whom had also taxed their resources, time and labor until it appeared almost impossible to continue under the strain. They deserve the good fortune that awaits them.

Blasting Without Drilling.—An exchange givee the following, which might possibly he utilized on the Comstock in some kinds of work: "An Austrian engineer, named Laner, has discovered a new method of disintegrating rock. The chief feature of his eyetem is to employ a hollow cylinder, like gas pips, and to plaoe the dynamite cartridges, not as hitherto in a hole bored into the rock to he hlasted, hnt in the cylinder in question. The cartridge only tonches the surface of the rock it is desired to shatter. The explosion of the dynamite ie effected hy electricity, and the effect is said to ho greater than with the nsual cartridge in a hole bored in the rock. The rock in shattered into fragments so small that a fair stream is able to wash them away without help, whereas in case of gunpowder, the rock is only split up into blocks more or less large and troublesome to remove. The Lauer eystem is calculated to save fully 40% as compared with the old system."

The Old Style.—A man was recently met in one of our mining districts driving along the road with a pair of mules and an old wagon.

"What lay are ye on?" asked a borseman who met him.

"Goin' up the cauyon to locate a mine."

"Can't locate no mine in that canyon. Can't find any pay ore."

"So I heard, so I hrought it along in this sack."

Teamster winks, holds up a chunk of $14,000 rock and they both take a drink.—*N. Y. Daily Stock Report.*

Candelaria.

A correspondsnt of the Virginia *Enterprise* gives the following concerning this mining camp:

Candelaria cannot hoast of her sevsn hills like ancient Roms. It is comfortahly nestled in ths mountains, which loom up on the north and south until their hlack outlines stand out in hold relief against the blue-vaulted heavens, while a thousand smaller peaks add variety to the landscape. We have no forest and no mountain torrsnts. To the wsst of Candelaria, on a heautiful eminence overlooking the town, is a miniatars city of ths noble red man, consisting of some rnde stone houses, a cress hetwesn tbe ancient Egyptian and the days of Adam. Thsse people find employmsnt around Candelaria. Some have become much civilized, "all same as white man," get drnnk, and swear and fight on the essence of bug juice. This is an age of progress, however. The white popnlation is iudustrious and temperate, as a rule. We have no churches or religious doctore to orate to us on Sundaye; no melodeons, and no operas. There are two bande—one string, the other brass. The latter numbers 11 instruments. Both do credit to the place. There is a school for dancing with 50 odd pupils, some of the heet young men of the place. I euppose this world is all a stage, and the refined lady and gentleman must he the vauguard of society. At present we aro all on the *qui vive* to see the locomotive some day march into Candelaria at double quick, and promenade to the eouth. I nnderstand that the railroad company is driving ahead. We will soon havs an ahundance of fine granite water from tho neighboring mountaius. Then we will he happy. Town lots have heon a shade higher within the past three months. The sound of the carpenter'e saw and hammer makes music all the day, fixing up for winter. Prices of firewood remain at the maximum of $18 per cord. Our merchants are laying in a large eupply, taking Time by the forelock, hsfore the approach of had roads and the cold, chilly storms of December. There is oonsiderable competition between the merchants. Our laboring population numhers between 200 and 300, exclusive of females, children and Chinese. The town is lively on pay-days. The mining population sustains its present prosperity. It has hesn the constant hlow of the pick and hammer that bas opened our fonntains of silver. Capital and labor have converted Columbus district into a human hive of indnstry.

Our mines justify all the money expended for their development. They extend over eight milee, rnnning west and southeast. We have some fine turqnoise, so much valued in jewelry, fire clay, petrified wood, plaster of paris, hesides a large vein of chlorides running through the distriot with hig croppings. In the future I will give a more elaborate account of the Columhue mineral zone.

The Poison of Human Saliva.

Recent observations hy M. Gautier, communicated to the Parie Medical Academy, afford reason for believing that the poison of serpents differs from that of human saliva in its intensity rather than in its essential nature, eo that the fears with which a human hite is often regarded may not ho wholly unreasonahle. To test this idea M. Gautier took eome 20 grammes of human ealiva, and, after lixiviating and purifying, obtained a substance which, injscted under the skin of a bird, in the form of a solution produced remarkable poisonous effects. Almost immediately tbe hird was seized with tremhling. It staggered and fell to the ground in a state of coma and complete stupor, terminated hy death in half an hour or an hour, according to the dose injected and the vigor of the animal. The phenomena resembled fully thoee prodnced hy the hite of a venomous serpent. The poisonous matter of the saliva ie thought to be an alkaloid similar to the cadaveric poisons called *ptomaines*, which MM. Brouardel and Boutmy have isolated. Like them, it produces Prussian blue when mixed with ferrocyanide of potassium. The facts stated throw some light on the question of virulent maladies. The present case, it ie pointed ont, is not that of a true virus; for at high temperatures a virne is destroyed, hut when the salivary alkaloid is heated to more than 100° its poisonous property is not affected. M. Gautier studied comparatively the poison of the cobra (one of the most formidahle of Indian serpents). This injected, in a dose of one milligramme in a quarter of a cubic centimeter of water, under the skin of a small bird, snch as a chaffinch or a sparrow, kills it in five to twelve minutes. One ohserves torpor and coma, then a period of excitatiou, with convulsions and tetanic contraction. In connection with the snhject, a correspondent of *La Nature* calls attention to a passage of Rahelais in which the poisonous nature of human saliva is recognized.

Ex-Congressman Thos. Wren, says the Winnemncca *Silver State* of Oct. 21st, passed through here yesterday, going west. He said what seemed to he the largest hody of ore ever discovered in Eureka wae found in the Richmond miue, hetween the 600 and 700 levels, last Tuesday. He considers it the moet important mining discovery of the year, and says "there's millions in it."

Several of the Arctic whalers have arrived in port, hut there is no news of the *Jeannette.*

MECHANICAL PROGRESS.

Points about Lathes.

There are details about lathes where improvements could be made that are worth considering: For example, suppose the front end of the tail spindle has a collar fitted to it threaded on the outside, so that we could take a chuck off the dead center and screw it on the spindle! Very often that would be an advantage on some work. We could take off a chuck with the work on it, screw it on the tail spindle, run the drill with the live spindle, and put holes anywhere about the work with the assurance that they were exactly true with the turned face. We could chuck a small eccentric or crank by the hub, turn the outside, change the chuck to the tail spindle, set over the tail stock, and bore the hole in the eccentric with the assurance that the job would be true.

Another point: When a tail stock is designed to set over, why should it not have a steady pin to enable it to be set to turn parallel again, such as some brass-finisher lathes have? Every turner knows how troublesome it is to set a lathe back, after turning a taper to turn parallel.

In one detail most lathes are too light, and it is such a minor point that it is always overlooked, or is in many cases within our experience, and this is the feather that holds the tail spindle from turning. Where a center only is used in the tail spindle, of course there is no strain to speak of; but some machinists have occasion to fit special tools in the spindle, as reamers or large drills, and in this class of work a light feather will not stand the strain. These are, perhaps, small things in themselves, but it is the detail that makes the tool—not the polish on it.—*Mechanical Engineer.*

COMBINED ANVIL, PUNCH AND SHEARS.—Mr. H. A. Schnelkloth of New York City, has invented a combination device, which answers for the triple purposes of anvil, punch and shears. The anvil is of the usual size and shape, the shank and base portions being hollowed out to receive the shear lever which projects from one end of the anvil, and the punch lever which projects from the opposite end. The fixed blade of the shears, as well as the female portion of the device, is arranged upon strong transverse base portions of the anvil, both being set into dovetailed recesses of the base. The base below the opening of the female die is provided with a hole of gradually increasing width, through which the punchings are readily dropped. The movable blade of the shears is attached to the front end of a fulcrumed lever, the rear end of which is connected by a strong link to a fulcrumed lever which carries the male die of the punching device. The shear lever is connected by a pivot link, with a vertically guided block, in which is formed the socket for the punch, this block being guided by beveled cheeks of the side walls of the anvil, and by an angular front plate. The link serves to raise the block, while a solid piece, interposed between the block and the end of the lever, serves to press the block down so as to force down the punch. The inner end of the punch lever is provided with a toothed segment which meshes with a pinion keyed to a transverse shaft, and provided with a lever by which either the punch or shears are operated according as the lever is thrown into one direction or the other. This shaft is journaled in bearings of the side walls of the anvil, and carries at its outer end a socket frame into which the handle is inserted and clamped when it is desired to operate either implement. In this manner a handy and compact combination tool for metal workers, which serves as an anvil, punch, or shears is obtained, which does not take up more space than a common anvil, and dispenses with separate punching and shearing implements.

THE LIFE OF A CAR WHEEL.—When the ordinary chilled car wheels were the only kind in use, 45,000 miles was considered an exceptionally good record for a wheel, while the great majority would run from 35,000 to 40,000 miles only. With the present steel-tired wheel, 300,000 miles' wear is not unusual, and wheels have even been known to live through 600,000 miles' service. A prominent New England railroad has about 1,900 of these wheels in use, the average life of which is 122,000 miles, many of them being new. From the number, 666 wheels which had been longest in use were selected, and the record showed an average mileage of 215,578. Among the number were 126 which had run over 250,000 miles, and 35 had a record of over 300,000 miles, while two had attained 490,915 miles each. It may not be generally known that railroads keep a record of every wheel in use, but such is the fact. Every wheel is numbered, and its life is traced by its daily service. The employees of the railroad are required to report the distance run at the end of each trip, and a record is made of the mileage of each wheel. Regarding the comparative cost of chilled and paper wheels, it may be said that while the price of the latter is considerably higher than that of the former, longer wear more than compensates for the difference. The ordinary chilled 33 inch wheel costs from $13 to $14, and the steel-tired wheel of the same size about $55, while the 33-inch paper wheel costs about $75.

Machine and Man Power in Production.

The census exhibits some curious and important facts, and none more interesting than the increased production of wheat over the increase of population in the United States. In 1849 the entire wheat product of the country was 4.33 bushels per head of population. In 1859 the total product of the same cereal was 5.5 bushels per head of population. In 1869 the product was 7.8 per head, while in 1879 the total product was 459,591,093 bushels, giving 9 bushels per head. Now this increased product per head is not to be accounted for on the supposition that a larger per cent. of population is going into agricultural pursuits each year, because the census shows that the contrary is the fact. Nor can it be accounted for on the supposition that there is an increased production per acre, for the same census disproves this proposition, and shows that the yield per acre over the whole country has neither increased nor diminished materially for the past 40 years.

We must seek an explanation of this increased ratio of production over population in the fact of the rapid improvement in agricultural machinery and in its more general use. Machine and horse and steam power is supplanting or supplementing man power, and rendering the exertions of man more remunerative—in other words, adding to the value and productiveness of man's labor. Laborers are apt to think that the more machinery is used in production the demand and compensation of labor will decrease, but the contrary is the fact. Wages have been steadily on the increase for the past 40 years, and have kept pace in that increase remarkably in proportion to the increased production of labor.

A NEW SECURITY AGAINST EXPLOSIONS.—The St. Louis *Age of Steel* says: "A Canadian mechanical engineer named Arnoldi has invented a device designed to give a partial security against boiler explosions. The invention consists of an electric adjustable attachment to the ordinary steam gauge now in use, to give an instant and continuous alarm, at any distance from the boilers or other pressure generators, of any excess of pressure over that at which the alarm has been set, and where there is more than one generator in operation, an ordinary 'tell-tale' can be attached to signify which generator is at fault. The invention possesses a great many valuable features, prominent among which may be noticed that it is extremely simple and inexpensive, and can be attached to existing arrangements at no expense beyond that of the alarm itself, and without in any way affecting the present adjustment of the gauge." This apparatus might be made very useful if placed beyond the reach of the boiler attendent, and connected by wire with the residence of the superintendent or owner of the boiler. It would, at night, especially, tend to keep a watchman on the alert, who might otherwise coal up the fires for a good rest, go to take a smoke or nap when he should be attending to his duties. It would be an easy matter, however, for a rogue to disconnect the wire, and thus defeat the object of the device.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS commenced its regular annual meeting in New York on the 3d inst. Although this will be only the second meeting since the organization of this society, yet it has so rapidly increased its membership, and has become so favorably known to practical mechanics as a live and progressive body that we bespeak an interesting gathering on that occasion. There will, undoubtedly, papers be presented and discussions carried on upon matters both theoretically and practically valuable to all those who wish to keep themselves abreast of the industrial questions of the day and much information elicited which cannot fail to be advantageous to the mechanical interests of the country at large, as well as to the individual welfare of its membership.

IMPROVED EMERY PAPER.—Emery paper is frequently found lacking in retaining an equal efficiency, the fresh parts biting too much and the paper getting soon worn through in many places. Emery has been tried on linen, but with little success. A paper or board has been recommended in which emery enters as a constituent part. It is advised to employ fine and uniform cardboard pulp, with from one-third to half its weight of emery powder thoroughly mixed with it, so the emery may be equally distributed. The mass should be poured out into cakes of from one to ten inches in thickness. They must not be pressed hard. Such a paper, it is said, will adapt itself to the form of the articles, and will serve until completely worn out.

TOUGHENED GLASS.—Though superior to ordinary glass, toughened glass has never yet taken its place, which is no doubt largely due to its extra cost. Mr. Frederick Siemens, however, now proposes adapting the toughened glass made by his process to the manufacture of lamp posts, water mains, etc. His glass, he says, is stronger than iron castings, imperishable and incorrodible, and though the price per lb. is twice that of iron, the specific gravity is so much less that the user will be able to obtain glass articles at about 30% less than the same goods in cast iron. Mr. Siemens promises this, but it does not by any means necessarily follow that he will perform, as it is no easy matter to upset the long accustomed use of materials.

SCIENTIFIC PROGRESS.

Chemistry in the Industries.

Chemists are steadily revolutionizing old processes and ruining old industries by their synthetic methods of making the counterfeits of natural products. The madder industry of France was the first to feel the power of modern chemistry, and now madder is a comparatively useless crop. The coloring principle which was so valuable to the dyer was analyzed by the chemist, and separated into its elements; but the chemist went farther; he found a comparatively waste substance which, by a little manipulation, would yield just the same elements as the madder root in just the same proportions. Consequently it must, except under special circumstances, be identical in constitution with the natural product.

The indigo planters of India are threatened with a similar extinction, for the coloring matter known as indigo has been synthetically prepared in the chemist's laboratory, and only awaits a cheaper raw material than the indigo plant to gradually bring about the decline of one of the most profitable crops of India.

Citric acid is another notable instance of the triumph of synthetical chemistry; and latterly a process of preparing vanilla, the essential oil of vanilla, has been patented in England. A majority of our flavoring liquids and the most delicate perfumes, which were formerly the result of slow processes of distillation, are now produced by chemical manipulation from inorganic substances. It is now almost impossible to purchase in the Eastern States or in Europe a genuine article of fruit jelly. Microscopical examination or chemical analysis shows that these preparations are now colored with chemical dye stuffs and sweetened with artificial sugar made from corn by the sulphuric acid process. By-and-by chemistry will make for us the most delicate perfumes and the most costly flavors out of the waste substances of other industries.

But chemistry has also its more legitimate fields of labor and research. It has become an almost indispensable assistant in all the large industries of the world. It has revolutionized the iron industry and that of the dyer, while both the farmer and the miner would now be completely at loss without its aid. It is constantly at work devising new methods for many of the minor industries. Our eyes have just fallen upon the two following items in this direction:

"The growing importance of magnesia in the manufacture of cements, artificial stones and fire-proof brick and other refractory materials, has led to a number of attempts to produce it from chloride of magnesium, found in such abundance at Stassfurt, Germany, and elsewhere. M. Closson, of Paris, has recently introduced the treatment of chloride of magnesium leys with burnt dolomite, and has thus produced very pure magnesia. At Leopolds hall, where the process has been introduced on a working scale, magnesia bricks have been made, which, according to *Chemical News*, have resisted even the flame of the oxy-hydrogen blast."

"A new method of preparing chlorine has just been introduced by J. Townsend, of Stassfurt, Germany, who accomplishes this purpose by mixing a heated solution of magnesium chloride, of 40° to 50° Baume, with about 10% of manganese dioxide, and then exposing it to the action of heated air, whereby the chlorine is liberated, which may be used in the ordinary manner. The process is facilitated by the addition of 25% to 50% of calcium chloride."

EFFECT OF PRESSURE ON SEED GERMINATION. In a note communicated to *Nature* by Mr. W. Carter, an account is given of the effect of pressure on the germination of seeds. He found that under a pressure of 2½ atmospheres, mustard seed germinated 25 hours earlier than under the ordinary pressure of the atmosphere; but that the early development became permanently arrested during the eight days of the experiment, and the cotyledons of one that had escaped entirely from the seed coat remained as etiolated as if grown in absolute darkness, while those under ordinary pressure grew rapidly, and their cotyledons became of a deep green color. The etiolated plants, when removed from the pressure, rapidly grew into vigorous young plants. An increased pressure would, therefore, seem to stimulate germination and prevent the formation of chlorophyl. The pressure was obtained by the use of a column of mercury. The seeds were sown on moist cotton-wool, placed in a small bottle, which was then secured to the curved extremity of a glass tube, into the long arm of which mercury was poured until it reached a hight of 45 inches above the level of the metal in the short arm.

THE CAMERA FOR DETECTING FORGERIES. The Bank of France is said to have almost wholly abandoned chemical tests in favor of the camera for detecting forgeries. The sensitive plate not only proclaims forthwith the doing of eraser or penknife, but frequently shows under the forger's figures the sum originally borne by the check. So ready is the camera to detect ink marks that a carte-de-visite enclosed in a letter may appear to the eye without blemish, while a copy of it in the camera will probably exhibit traces of writing across the face, where it has merely been in contact with the written page.

"COSMICAL DUST."—Dr. Lasaulx has investigated the subject of "cosmical dust," a mineral dust collected at different times at various points of the earth's surface, to which a cosmical origin has been assigned. A portion of the original material from the interior of Greenland, collected by Nordeoskjold, and named by him *cryoconite*, was examined microscopically and was found to be not even approximately homogeneous. On the contrary, the dust was made up of particles of quartz, mica, orthoclase and triclinic feldspars, magnetite, garnet, apidote and hornblende, and, with these, brown or brownish-green particles of organic nature, probably microscopic algæ. Dr. Lasaulx concludes, from the absence of augite and chrysolite, that the dust could not have come from a volcano, but that it was derived from the gneissoid rocks on the coast of Greenland; that there is no reason to think of a cosmical origin for it, and the presence of quartz and mica declare against this idea. The dust of Catania, Sicily, which was described by Silvestri and has been regarded as cosmical, Lasaulx has also investigated. His conclusion is that all the materials present in it could have been, and in all probability were, derived from Mt. Etna. A study of the residue by the melting of a large quantity of snow collected by the author in the neighborhood of Kiel, revealed no minerals for which anything but a terrestrial source need be predicated. In conclusion, Lasaulx decides that the atmospheric dust is in general to be regarded as terrestrial detritus, and that before a non-terrestrial origin can be considered proved in any case, a much more critical microscopic examination must be made than has been customary in the past.

THE SURVEY OF THE NORTHWEST.—Mention has been made of the projected scientific survey of the country tributary to the Northern Pacific railway and the Oregon railway and navigation companies' lines, under Prof. Raphael Pumpelly. The work, which will be organized for a term of years, contemplates mapping the country "on a published scale of four miles to the inch," in order to show the geological structure, the distribution of minerals, of the different varieties of soils, of plants and animals, and the climatic conditions. For the thoroughness and high scientific quality of it the director's name is a guaranty, but he has also associated with him a number of trained men from the United States Geological Survey, including Mr. Wilson, the able topographer of the Fortieth Parallel Survey. The classification of the lands of the railroad companies according to their fertility and their mineral and timber resources will, of course, furnish a rational guide to the extension of branches, and will have a wholesome effect in turning immigration into remunerative channels. The bulletin which the survey contemplates publishing will thus be eagerly consulted. Meantime, the Signal Service will welcome the new meteorological stations to be established in the pre-eminently weather-breeding section of the continent. In every way the country at large will profit by this nominally private enterprise, which anticipates the national exploration of the great northwest territory.

OZONE AT THE PARIS ELECTRICAL EXHIBITION.—The editor of *Les Mondes* has had a call from Dr. Tommasi, the distinguished Florentine chemist, who came to propose an idea to him that is worth publishing. The Palace of Industry is at present a place where there is in circulation, especially during the evening, an immense quantity of electricity. Now, under the special and entirely exceptional conditions presented by this vast closed space saturated with electricity, it may be that the atmosphere undergoes peculiar modifications; for example, there may be a production of a certain amount of ozone. It would be extremely interesting, then, to put up an apparatus for collecting the ozone from the air, and which should work continuously at the exhibition. Such an apparatus was proposed by Dr. Tommasi at London seven years ago. The moment seems to us opportune to perform these curious experiments. Dr. Tommasi is all ready to undertake them, but he needs for this the concurrence of some of our learned professors and the kind co-operation of the commissariat of the Electrical exhibition. We trust that neither will be lacking. Should these experiments take place we will inform our readers of the results obtained.—*Chronique Industrielle.*

SOUTHERN NEW JERSEY SINKING.—Prof. Geo. H. Cook, State Geologist of New Jersey, concludes that the land in Cape May and Cumberland counties is gradually but certainly sinking. From knowledge now in his possession he estimates that the surface has settled about eight ft. during the last 100 years. During a recent visit he declared it his intention to test the matter by placing stone posts in the ground at certain localities, a record of which should be kept so as to insure their being found at any future time, said stones to be so set and marked with reference to their hight above the sea level that it may be positively ascertained whether this portion of the State is becoming lower, and at what rate.

EXTINCTION OF ANIMALS.—According to the Paris *La Nature*, all of the larger animals the world over, including the lion, tiger, gorilla, giraffe, elephant, hippopotamus, etc., are rapidly approaching extinction. Some are hunted down for profit, some for pleasure, and many because they threaten the existence of man.

The Mining Share Market.

There is nothing much doing in mining stocks, very little activity being shown. Good progress is now being made at all points along the Comstock. There are at no point either water troubles or serious troubles of any kind. The *Enterprise* says there will probably soon be assessments levied by the Savage, Hale & Norcross, Chollar and Potosi mines, for the purpose of paying for the big hydraulic pump at the Combination shaft, said pump having been accepted by the companies interested in it. The sooner this assessment comes and is paid the hettor for the stockholders. The amount to be raised by each company is not large. The dread of this assessment has for a long time kept down Savage, Chollar and the stocks of all the companies interested. Once this assessment is paid, persons will think nothing of paying $2 or $3 a share more for these stocks than the present prices, yet while it is impending all will hold aloof.

The receipts of hullion from the mines during the month of October were as follows: Bodie, $30,046; Bechtel, $19,041 94; Bodie Tunnel, $5,028.73; Christy, $28,634. Eureka, $115,-992.19; Emigrant, $16.000; Head Center, $18,-921; Northern Belle, $89,724.22; Oro, $8,228.-60; Ontario, $167,443.96; Star, $22,100.20; Standard, $164,632.08; Syndicate, $6,020 44; Silver King, $72,763; Wai Wera Consolidated, $6,866 99; Western, $94,262.64, making a total for the month of $865,705.99. The total for the month of September was $948,578.11; in August, 1,296,595.61; in July, $1,663,387.76; in June $1,425,885.42; in May, $1,078,354.15; in April, $1,125.383.81; in March, $1,134,-096.08; in February, $1,324,069 80, and in Jannary, $100,163.43, making a grand total of $11,933,146.08 for the first 10 months of 1881.

The following companies report a cash balance on hand November 1st: Alta, $28,729.52; Alpha, $4,441; Argenta, $1,520.46; Benton, $487.82; Bodie Con., $11,113.37; Bulwer,$104,-140; Belding, $923.82; Belle Isle. $2,367.03; Bechtel, $24,155.56; Chollar, $8,111.48; Challeuge, $559.75; Caledonia, $512; Crown Point, $31,991; Con. Virginia, $24,337; Donble Standard, $5,994.31; Gould & Curry, $9,103.24; Gen. Jackson, $7,524 91; Grand Prize, $1,-426.37; Holmes, $991.27; Imperial, $10,938.23; Julia Con., $9,261.62; Justice, $25,207.44; Lady Washington, $2,380.49; Mount Diablo, $173.33; North Belle, $91,680; Northern Belle Isle, $1,567,19; New York, $2,500; Standard, $349 914; Saratoga. $7,739.94; Silver Hill, $17,-658.93; Tioga. $13,414.32; Western, $3,303 11. The following were named in debt: Best & Belcher, $1,381; Bullion,$50,000; Betty O'Neal, $4,576.46; California, $23.652; Day, $74,407.-92; Hale & Norcross, $4,500; Mono, $166.36; Overman, $5,246.40; Potosi, $12, 347.71; Sierra Nevada, $29,875; Union, $19,149.31; Utah, $7,398. The Bullion Mining Co. has $85,787.17 resources to meet the above indehtedness and the Octoher expenses at the mine. California as $9,141 unsold bullion.

Meetings and Elections.

Western M. Co., Nov. 7. Directors: A. K. P. Harmon (President), John H. Boalt, John F. Boyd, D. C. Bates (Secretary) W. S. Marks.

A resolution was adopted forming a new company, to be known as the "Contention Consolidated mining company," with a capital of $12,500,000; divided into 250,000 shares. The formation of the new corporation involves the consolidation of the Western, Flora Morrison and Sulphuret. The apportionment is made as follows: Western to receive for its mine 200,000 shares; Flora Morrison to receive for its mine $32,000; Sulphnret to receive for 600 ft of the southerly end of its mine 18,000 shares.

The Western declared a dividend of $1 per share payable on the 10th inst., and there will be another final dividend in settlement.

The gross product of the Western mine is given at $1,502,742 39. It has paid $900,000 in dividends during the past year, and the dividend declared yesterday will bring the amount disbursed up to a round million.

POPULAR SCIENCE MONTHLY.—The *Popular Science Monthly*, for November, fully holds its well earned reputation of being the best magazine in the country for the sonnd education of the people. There is never a page of trash in this sterling publicatioo. All its numbers in all the 20 years of its existence have heen good ones. Its articles are always able, instructive, fresh and repleto with original thought. Herbert Spencer opens the present number with an article on "The Industrial Type of Society," the eleventh in his series on "The Development of Political Institutions." "Volcanoes, their Action and Distrihution," is a very valuable article, profusely illustrated, and designed to correct many popular errors in regard to volcanic phenomena. Dr. Felix L. Oswald continues his papers on "Physical Education," the present number being devoted to the topic of "Hygienic Precautions." The many extracts which have been given from these papers in the columns of the PRESS cannot have failed to impress upon our readers their great value. "A Half Century of Science," an extract from the address of Sir John Lubhock before the late meeting of the British Association for the Advancement nf Science, gives an interesting resume of scientific progress for the last half century. Those interested in "other worlds than ours," will he especially pleased with an article hy Francis Brigham on the discovery of "Organic Remains in Meteoric Stones." The present number is embelished with a finely executed portrait of Geo. J. Brush, of the Sheffield Scientific School, accompanied with a brief sketch of his life. The various minor departments are well filled with a good variety of instructive and useful reading. New York. D. Appleton & Co. $5 per year, 50 cents per number.

ARTESIAN WELL TUBES.—In the last numher of the PRESS we described a constrnction of artesian well tubes as having been patented by Benjamin Roberts. The name was incorrect. It was B. R. Norton, of Alameda, who obtained the patent.

WHILE hydraulic mining is, for the present, quiescent, gold quartz mining will receive a new mpetue in California.

MINING SUMMARY.

The following is mostly condensed from journals published in tho interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

PURCHASED.—Amador *Sentinel*, Nov. 2: The Monterichard mill has been purchased by the company working the Owen Kelley mine, and will be transferred to the latter point. A 60 inch flow of water burst out in this mine on Friday eveuing, necessitating a few day's suspension of operations.

AMANOR GRAVEL CLAIM.—This claim, located two miles east of Jackson, is to be started up for a final effort to hunt up a paying lead. For over a couple of years mining has been carried on, with brief intervals of suspension, at a loss to the stockholders. It seems no pay-dirt has been struck to amount to anything so far. The stockholders, however, have determined to pungle up a few more thousands to fossick around the ancient river bed supposed to lie in that vicinity. If the search thie beat prnves fruitless, it is probahle that the river of geological times will be let severely alone by the stockholdere henceforth and forever.

EMPIRE.—Of this mino nur Plymouth correspondent writes: Last Saturday, ou the night shift, 125 buckets of ore were taken out through the south shaft. Ono hundred tons of rock extracted from the north side of the mine have been crushed at the mill. How it yielded I am unable to say.

PACIFIC.—On the 80th nf Octnber the station was finished and on the following day drifting was started, and more men were put to work. Plymouth is increasing in population every day.

MEDIAN.—A clean-up of the test run of ore from this mine was made at the Talisman mill this week. We are not able to give the exact yield, but it is eo satisfactory that the stamps were put in motion again as soon as the clean-up was completed. The outlook is favorable for a permanent and paying mine.

MISCELLANEOUS.—The shaft of the Maryland is down 400 ft, and drifting for the ledge has commenced with encouraging prospects. We have heard nothing further concerning the developments of the tunneling operations at Murphy's ridge.

OLETA ITEMS.—Mining has been started with energy in every direction. Purington & Clark are working a large force of hands on their gravel claims at American flat and vicinity. B. Bacon has recommenced work on his claim. Mr. Bacon has made some good clean-ups in the past. The Bradegon brothers will commence work soon.

VOLCANO.—The Golden Gate hids fair to become one of the permanent mines of the county. Sinking is progressing, and good rock is being taken from the shaft. The works are in first-class order. The lode widening as the shaft descends, and the ore growing richer. Supt. J. W. Moyle is at the Bay at present. The Downs mine continues to produce rich ore, of which there appeare to be no limit. The mill will soon be erushing again, as water is beginning to appear in the d tches. This will add much to the output of the precious metal from this section. Robt. Stewart's mine, on the Mokelumne river is taking out richer ore than ever; the ore works at the mill from $18 to $75 per ton. The mill is running constantly. The Volcano G. G. M. Co. will have completed by Saturday, a 7-ft flume, designed to carry the waters of the South Branch creek over the excavation at the mouth of the tunnel, which will prevent the filling up in case of very high water. It is a fine piece of work, and substantial. Supt. Barling has put in a regular railroad trestle bridge which suports the flume.

CALAVERAS.

WEST POINT.—Cor. Calaveras *Chronicle*, Nov. 5: The mining district of West Point is blooming out at last. From every point we hear of new developments, and also a number of new strikes, which, taken as a whole, give this place a prominent part in the gold mining interests of California. 'Tis true not half of our mines, or say one-quarter, are at present being worked, but those that are, fully deserve to be brought before public notice in order to encourage the prospecting of those mines that are at present idle. From the Champion mino we hear good news. A vein of quartz has been struck in the bottom of the 700-ft winze which measures 6 ft across it and prospects at the rate of $60 per ton. The owners are jubilant, and intend to increase their present working force. The Florida mino is also making a splendid showing under the supervision of Mr. Ferguson. The 190 level has been carried farther in, and quartz of exceeding richness has been found; a new pay chimney has also been struck on the south side of the present working shaft, about 150 ft from the present workings. The quartz shows plenty of gold and sulphurets, and it appears, in both this mine and the Champion, slate formation is beginning to appear as depth is attained. Mr. P. Bushman has struck a fine body of quartz at Camp Flores. The vein is 3 ft wide and all pay rock. Reuter & Eberhardt have also struck rich quartz in the Blazing Star mine. Smith & Co. have been putting up an engine on the Pride of Bummerville mine. W. Moore & Co. are taking out rich rock from the old Bowers claim. W. Steger & Co. are also taking out good quartz from the Anna mine; about 20 tons on dumps. The owners of the French lode have struck "ounce" rock in the bottom of their shaft.

BULLION.—I made inquiries, and for a few of which I can give a correct account of the amount of gold bullion produced in and around this district during the past two weeks:

Champion mine	$6,000
Riverside	900
Constitution	816
Jackdaw	632
McGee	510
L. Morse mine	442
Mexico	355
Pride of Bummerville	300
Whiskey lode	816
Blazing Star	300
Total	$11,161

Besides this quite a number of smaller amounts both from placer and other sources have been taken out, the quartz from the above mentioned mines averaging $60 per ton.

EL DORADO.

THE SPRINGFIELD MINE.—*Mountain Democrat*, Nov. 9: This noble mine, the mainstay of Mud Springs township, is just now looking and paying better than at any period of its prosperous career. The tunnel on the 700 level has opened up two pay chutes, larger and richer than the same chutes were on the upper levels. There are four of these rich chutes or clumneys that have been worked on upper levels, and there is no room to doubt that the other will in due time be reached on the 700 level. A tunnel is also being run on the so-called 900 level, though the actual depth of this level is about 080 ft. This tunnel, it is calculated, will reech the first of the pay chutes in about 200 ft. In the meantime the mill is pounding away on rich ore and making satisfactory returns. The current opiuion of the neighborhood is that a large share of the success of the Springfield mine is due to the sound judgment and indomitable energy of its Supt., L. R. Poundstone.

FRESNO.

ENTERPRISE.—Mariposa *Herald*, Nov. 5: At present there are a great many mines, but very few mills for crushing purposes in this section. Parties with capital could not invest in anything that would pay better than a good mill for crushing custom rock.

A PARTY of English capitalists from San Francisco were up last week looking at the Gambetta mine, and talk is that a sale was made for $150,000.

MINE SOLD.—We are informed that the Amee mine, situated between the Enterprise and Ellen mines, Grub

Gulch district, Fresno county, has been sold to Warren Luce, of San Francisco.

Bio Strike.—French Joe, a man well known in the vicinity of Fresno Flats went out prospecting a few days ago, and brought in a bathful of very rich rock said to contain about $2.0 to the bat. He won't tell where he found it.

Work has been resumed on the Butterfly mine, a good piece of mining property that has been lying idle for some time. It is owned by Thompson & Collins.

Mill Running.—The Enterprise mill has started up, and at present there is plenty of water. The recent rains in that section were very heavy, and prospects are there will be a sufficiency of water to run the mill until the rainy season sets in.

INYO.

Mexican.—Bishop Creek *Times:* The Mexican mine, situated on the south side of Redding's canyon, about 8 miles distant from Bishop Creek, and owned by Jake Ekeles, Jose Maria Portella and Francisco Cantuar, made a very rich strike on Saturday last at a depth of 10 ft. The ledge encountered is 5 ft wide, with 3 ft of ore that assays from $200 to $300 in gold, and $100 in silver. The owners are jubila t over the strike, and say they would not take $30,000 for the mine at the present time. The strike was made in the incline, which they propose to sink immediately to a depth of 80 ft, before running crosscuts to ascertain the extent of the ore body. They also have a tunnel in a distance of 15 ft, the face being in a ledge 5 ft wide, and which assays from $20 to $25. An arastra is kept running which yields enough to pay all expenses of developing the mine.

Gold Hill.—Wm Crapo, of Cerro Gordo, is about transporting some 10 or 12 tons of ore from the big Gold Hill ledge, situated about a mile north of the old Lower Town, to the arastra west of Lone Pine, for working for gold. It will be expensive, but the ore is rich and apparently inexhaustible.

Virginia Con.—Mr. E. Chenot, Supt. of the above mine, which is situated on Kearsarge mountain, has several men at work taking out ore. An average sample sent to the Independence assay office yesterday yielded gold, $32 01; silver, $175.93, total, $208 54.

Gold.—The owners of the Keynot mine at Beveridge, have shipped during the past month $18,000. The run will last until the 10th of this month, when they calculate to have $15,000 more, making $30,000 for the month, or $1,000 per day.

The Average Yield —The Keynot, or Mexican mine, is still yielding ore sufficient to run a 20-stamp mill, and the ledge is increasing in size, as well as in richness. The shipment, from 9 tons of ore per day is now averaging $1,000.

Work.—The old Fish Spring arastras are about to be started up on ore from the new gold ledge, recently discovered by Herne, in the Sierras to the southeast of the placer diggings west of Big Pine.

As Work.—The Taylor mill in Beveridge district, is running night and day upon Keynot ore, and with its five stamps crushes 9 and 10 tons of rock every 24 hours.

The Laura.—Inyo *Independent*, Nov. 5: We have been shown some very fine samples of ore taken from the Laura, in Beveridge district, assaying from $225 to $500 per ton. About 100 tons of ore are on the dump, which will net over $10,000. In this whole country, so vast, and rich in its mineral resources, there is at present no better or more promising prospect than the Laura. The ledge crops out in bold relief along the entire length of the claim, and is rich paying rock from the surface. Considerable developments have been made.

The Montezuma.—The Montezuma, or what is better known as Billy Lake's mine, situated in the Inyoa opposite Fish Spring, is under bond, some $500 of the purchase money paid for it, and active work of development is going on. Mr. A. H. Griswold, a mining man of long experience, has this enterprise in charge, representing a strong San Francisco company. The ledge, or deposit, shows an enormous outcrop of argentiferous galena, and to open it by sinking is an easy going thing

NEVADA.

Chanoko Hands.—San Juan *Times*, Nov. 5: It is rumored that the American company's mining property has changed hands; that on Monday last the property was transferred to the Yuha tunnel gold mining company, a corporation—such is the rumor. Whether true or false we know not, but this we do know, that if true, the Yuba Co. have an elephant on its hack which only requires, in our humble judement, the down off a goose's back to break to pieces. We think that the Yuba Tunnel Co. had experience enough not to again enter into this enterprise of mining, especially in the locality of the American mine. It is true the present stockholders of the Yuba Tunnel Co. are not the same men that sold out to the American Co., but nevertheless they cannot put gold in ground where there is none. If it he true that the property has changed hands, we will congratulate the members of the American Co. for ridding themselves of an incubus. The ground will for a time perhaps pay water money and expenses of working, and that's all.

PLACER.

North Fork Dam.—Placer *Herald*, Nov. 5: We learn from S. Washburn, superintendent of the Bear River, North Fork and Gold Hill ditches, that the fine, large, new dam on the North Fork of the American river, at the head of the North Fork ditch, nearly opposite Auburn, is substautially completed. The last work, except a few finishing touches, having been done last Saturday. By those who have seen it this is said to be a very fine structure. A large force of men have been employed in its construction nearly all summer, and it is gratifying to know that it has reached that stage which renders it safe against any unusually early flood that, any seaon, is liable to occur.

The Mining Situation on the Forest Hill and Iowa Hill Divides.—A gentleman who has spent the summer on the Forest Hill and Iowa Hill Divides, and who in that time has visited all the mining camps of that region, including Forest Hill, Michigan Bluff, Iowa Hill, Wisconsin Hill, Damascus, Canada Hill, Yankee Jims, Todd's Valley, Sunny South, Deadwood and Last Chance, reports that portion of Placer county in a very prosperous and promising condition. Most of the mines are paying well, and various recent developments are of a decidedly encouraging character. At Last Chance all the mines are paying. At Deadwood the miners are cheerful and say their claims are behaving nicely. The Weeks mine, near Michigan Bluff, is at present doing very well, and the Baker Divide in the same locality, a new claim, is showing very encouraging prospects. At Canada Hill, Johnny White is fitting up the Reed claim for drifting, with every assurance of big returns. Snyder & Hobson on their claim near the Secret House, are putting things in shape with confidence of flattering returns. The Hidden Treasure at Sunny South is too old, extensive, rich and reliable to need comment. The Mountain Oate at Damascus, now in the large, new, blue chanuel, is paying better than it ever did. The Succor Flat drift mino, near Wisconsin Hill, is, as usual, doing well, and in short, all over those two divides, our informant says, much money is being taken out and the prospects for more are very hopeful. He had never been much in that region before, but he thinks it are exceedingly rich country, and is of the opinion, (which is shared by many old miners) that its wealth has but yet been grazed.

An Important Mining Project.—Flanagan & Shaddock have been at work most of this last summer in fitting up a hydraulic elevator on the Middle Fork of the American river, a few miles above Auhurn, near what has been known as Hoosier Bar. Besides the labor necessary for the work they have spent a good deal in necessary pipe and machinery. They are now, we understand, after several experiments, running steadily, and our information is that they are finding the ground in the hed of the river very rich. If this enterprise proves a success, and the present indications are that it will, the old river beds of California which contain millions will inovitably become again the scene of active operations. All that is needed is to get at the wealth ths rivers contain, and if this hydraulic elsvator can supply ths need, it will prove a great thing. It will work a revolution.

PLUMAS.

Going for Bedrock.—Plumas *National*, Nov. 5: Mr. Mills has a boring machine at work at his shaft in the valley, and the anger is making rapid progress toward bedrock. This will determine the depth, and the character of the ground, and when bottom is reached it will be easy to calculate on the cost and necessary machinery for the working shaft.

Elizabethtown.—Messrs. Corbin & Manson are pushing their work along at a lively rate, and are reported doing well. The upper works are in good paying gravel, and the prospects in the lower shaft are improving daily, giving substantial reasons for thinking that the pay lead goes down the flat. If they demonstrate that, they have got a claim that will last a lifetime.

Jackass Mine.—Mr. Bell has been prospecting in the extension of the Jackass quartz ledge for some time, and has a shaft down 18 or 20 ft, showing the vein about 7 ft wide. The rock prospects well, and occasionally a piece shows free gold; There is no doubt but that this ledge will be a permanently good one, and we hope it will be thoroughly developed The owners intend to tap it at considerable depth from the Black Hawk side of the mountain, and work in the tunnel will commence in a short time.

SIERRA.

Results.—*Mountain Messenger*, Nov. 5: The result of last week's mining at the Extension mine, 6 men working on a shift, was 84 ozs of gold, worth nearly $1,600. One piece weighed 20 ozs, and several weighed from 1 oz to 3 ozs. Owen Thomas, of Eureka, thinks the future prospects of the mines in his locality were never more promising than now. Chas. F. Byrne, superintendent of the Truckee mine, near Rocky Point, Sierra county, came into town Monday and will remain during the winter. The mine has been closed down, and operations will not be resumed till spring.

TRINITY.

Waiting for Water.—Trinity *Journal:* Most of the miners in Trinity county now have their claims prepared for winter work and only await the coming of water to commence active operations.

NEVADA.

BRISTOL DISTRICT.

Ore.—Pioche *Record*, Oct. 20: Messrs. Gilmer, Salisbury and party last week made a thorough inspection of all the leading mines in and around Bristol district, and were decidedly pleased with what they saw, particularly so in the Tempest and Mayflower, where, in each, there is over 10,000 tons of ore in sight worth at least $50 per ton, or $500,000. The Day mine was also examined and pronounced by all to be one of the leading mines in the State, and, judging from the immense amount of ore in sight, Mr. Gilmer said he saw no reason why the Day, in time, shouldn't be on a dividend paying basis.

Mayflower.—Another large body of high-grade ore was encountered in the Mayflower last week while running the east drift from bottom of winze No. 1. It is from 7 to 8 ft wide, and runs all the way from $125 to $200 per ton. The sum of $200,000 was offered for the mine 10 days ago and refused, and since the finding of the new body of ors, which has increased its value two-fold or more, the Bristol Co. would probably take no less than $750,000 for the entire property.

Suit for Damages.—The Bristol S. M. Co. has commenced a suit for damages against W. E. Griffin, J. V. Keeley, Sheriff McKee, Deputy Sheriff Craig, O. Sherwood and George S. Sawyer for the sum of $54,000, for attaching and holding their property.

There is renewed activity in prospecting here, and numerous old claims will this winter be worked and opened up. The Day furnace is daily turning out 5 tons of bullion averaging from $350 to $430 per ton.

CANDELARIA DISTRICT.

Mount Diablo.—*True Fissure*, Nov 3: In the north crosscut from the east drift, from the bottom of winze on the third level, there is a low-grade ledge in the face. The north crosscut from winze No. 3 is in 67 ft and shows a favorable formation in the face.

Northern Belle.—The shaft levels have shown no change of note but are looking full as well as at the time of last report. The usual amount of work is being done in the adit and the levels above. Eighty-six tons of ore are being extracted and sent to the mills daily. Both mills are running steadily, mill No. 1 on half time. Bullion shipments for week ending Nov. 2d, $22,090 13. Total shipments on October account, $86,724 22.

Metallic Equator.—A full force of men is at work, and everything about the mine is running at top speed. The shaft is being sunk and good progress made daily. On the 400 a station has been cut out and a crosscut started. The station is large and roomy and sufficient for all work that may be done from it into any of the adjoining country. The new donkey pump and engine is working like a charm.

The Holmes.—Work is being carried on with vigor at this mine and fair progress is made daily. Fourteen men are employed in and around the mine, and they all seem to be moving in a hurry.

COOPER DISTRICT.

Another Discovery.—*Ward Reflect*, Nov. 2: Tom Sutherland and N. B. Dunton discovered a ledge in Cooper district last week, between Coopor pass and Steptoe creek, ore from which assays $180. They are well pleased with the prospect and work will be commenced at once.

DUN GLEN DISTRICT.

Auburn Mill.—*Silver State*, Nov. 1: The building for the C. O. M. Co's. mill at Dun Glen is completed, and the machinery is being put in place as rapidly as circumstances permit. Supt. Hodges expects to have 10 stamps running early in December. Much of the machinery is here yet, as it is hauled to the mill only when wanted, and the millwrights are prepared to put it in place.

EUREKA DISTRICT.

Important Strike.—*Sentinel*, Nov. 6: On Thursday last, in the Richmond mine, between the 6th and 7th levels, an extensive cave was discovered, which contains a vast amount of the richest ore ever struck in the mine. The probabilities are that it will exceed the celebrated Potts' Chamber. The company are to be congratulated upon their recent finds.

GRANTSVILLE DISTRICT.

Closed Down.—*Bonanza*, Nov. 5: Orders came from San Francisco on Thursday evening to suspend operations in the mine and mill of the Alexander Mining Co. At the time of closing the mines never looked better. How long the mines will remain shut down is a mystery too hard for outsiders to solve.

PIOCHE DISTRICT.

No Men Wanted.—Pioche *Record*, Nov. 1: Men in search of employment will do well not to come to this vicinity in search of that article. At the present time our labor market appears to be well supplied. There have been a number of strangers straggled in from Utah and Montana lately.

STAR DISTRICT.

Ooon Returns.—*Silver State*, Nov. 5: A carload of ore shipped by Peter Woolcock from the De Soto mine at Star, about two weeks ago, assayed $750.31 to the ton. That is a very fair average even for the De Soto.

TAYLOR DISTRICT.

Two and a-half tons of ore from the June mine at Taylor, were recently shipped to Eureka for reduction that went 233 ozs. to the ton, as shown by returns received Friday last.

Sale of Mining Property.—Robt. Briggs Saturday last purchased Esau P. Weaver's interest in the Breechloader mine, for $1,000.

The ore now being extracted from the Monitor mine is reported to be much richer than any yet put through the mill.

Another Sale.—Theodors Webb yesterday purchased one-fourth of the Juue mine, from John Murphy, for $250.

WARD DISTRICT.

Martin White.—*Ward Reflect*, Nov. 2: The superintendent's letter says: All work is going on well, and we are taking out some fine ore. In a short time I shall have most of the ground secured, when I can put more men on ore and in following out some very fine streaks. My object is not to take out a large amount now, but to so open up the mine that we can take it when needed. We are getting some rich ore as ever came out of the mine. The people of Ward have somehow got it into their heads that the ore body encountered is marvelously rich, and in that respect no mine anywhere approaches it, also that the ore body is very large, but, of course they don't know it for a fact. The superintendent is evidently more than satisfied with what is in sight, but prefers to underestimate rather than make a mistake on the other side.

WASHOE DISTRICT.

Ophir.—*Enterprise*, Nov. 6: The joint Mexican east drift on the 2000 level has been extended 25 ft. During the week 202 tons of ore have been extracted from the croppings, and 210 tons have been shipped to the mills.

Sierra Nevada.—The joint Union Con. east winze, 2700 level, has been sunk and timbered 8 ft. The west drift from this winze has been extended 25 ft; the joint east drill hole has been extended 210 ft.

Union Shaft.—Still rotimbering the drift running to the Sutro tunnel on the 1000 level, casing timbers at the 2000 station and cutting out a bob pit at the 2000 level.

Con. Virginia —We are still opening out and repairing drifts and winzes connecting with the old Con. Virginia shaft.

California —On the 2700 level the joint Ophir east drift has been advanced 25 ft.

Mexican.—In the Union Con. east winze a station is being cut out at the 2700 level. Have completed the new line of compressed air pipe in the main lateral drift.

Union Con —In the joint Mexican east winze are cutting out a station at the 2700 level. The joint Sierra Nevada west drift has been extended 25 ft, and the joint Sierra Nevada east drill hole 210 ft.

Yellow Jacket.—The north lateral drift, 3000 level, was run 21 ft, making length of same 03 ft from north winze. The drill hole west at foot of north winze is in 150 ft. Drilling shows quartz and porphyry. No change in quantity of water pumped.

WHITE CLOUD DISTRICT.

White Cloud Copper Mines.—*Silver State*, Nov. 4: E. C. Asher, Jr., of Lovelock, informs us that W. S. Bell, of Oakland, has purchased nearly all the mines in White Cloud district owned by George Lovelock and Joseph Organ. These mines are situated about 35 miles east of Lovelock, and are very extensive, and carry a high percentage of copper.

ARIZONA.

Important Sale in Tombstone.—The most important event in mining circles since the consolidation of the Flora Morrison and one-half of Sulphuret with Contention, is the purchase by the Boston mill company of the Stonewall mine, the deed for which went on record yesterday. The consideration paid for the mine was $100,000, and is considered a good investment at those figures. The company knew just what they were getting by the purchase, having worked several tons of the ore, which has given a return of $80 per ton. The mine is so far opened that it is safe to say they have the full purchase money in sight, with an assurance that as greater depth is attained and the full length of the ledge explored, they will have a mine that will rank with the bonanzas near town. This mine is located about 1½ miles south of town, at the point of intersection of the Merrimac mineral belt with the Tombstone belt proper. The Tombstone belt starts in at the San Pedro river and continues on in an unbroken course direct to the big wash north of town and possibly, as many good experts argue, clear through to the Dragoons. The Merrimac belt comes in at almost a right angle and abuts up against the main belt at or near the Stonewall. The course of this lode, as also that of the Contact, a few hundred yards farther south, is nearly due east and west. It is a true contract vein lying between lime on the north and quartzite on the south. The ore is an oxide of manganese, carrying green horn silver, and works perfectly free.

Globe District.—*Silver Belt*, Nov. 3: Stonewall No. 1 is developing into a reliable mine. It is not giving fancy assays but it is working 37 ozs to the ton. The vein is never small, and at times widens out to 12 ft, all of it milling ore. It is remarkably free, working up to 996 fine without refining. A strong stone wall has been erected back of the smelter to carry the dump and feed platform. The road has been finished to the platform. The road to the Illinois No. 1 mine is nearly finished. The working shaft on the South Pioneer is down 100 ft. It was started about 80 ft from the vein, and west of it. The vein has a westerly pitch of about 45°. At 93 ft a small stringer of quartz carrying ruby and other silver minerals was encountered, which, at 100 ft has widened out to 12 inches of ore possessing the same characteristics as the main vein, with the addition of polybasites, the same as the Silver King's. General McDonell is making rapid progress on his copper works. The roof is on the engine house, the assay furnace finished, the machinery all set, and the foundation for the derrick finished. The pump has been tried and works admirably. There will soon be a sale of the McCormack Co.'s mine and plant.

COLORADO.

Dunderburg.—Silver Plume *Coloradoan*, Nov. 3: We are glad to be able to give even a few items of information of what is being done in this mine. It is putting out the usual amount of ore and the grade is increasing in quality. One hundred and twenty men are employed. New ground is being opened by drifts and shafts in proportion to the amount exhausted in stoping, thus always keeping reserves sufficient to employ a full force of men in breaking down and taking out ore, a model which all of our large mining companies should follow, as on this principle depends in a large degree the future productions of the mine. By working on this principle the Dunderbarg is, and will continue to be one of our most steady ore producers. The present production of the mine averages about 115 tons per month, sometimes going as high as 130 tons The company are putting up an additional ore house 30 by 14 ft.

Shively.—Below the 255 level they are sinking on 2 inches of ore, the second-class milling 400 ounces and third-class over 600 ounces. They are also raising a mill hole for ventilation, in which they have 1 inch of ore of the same grades as above; 13 men are employed.

Stevens.—Shaft sinking is the order of the day here, which the workmen are doing on 1 foot of ore. The shaft is 4 by 12 ft. The engine is now in place and working well.

Atlantic and Pacific Tunnel.—Reports have been in circulation that work had ceased on this enterprise. We are glad that we are authorized to contradict them.

Tip Top.—This is one of the numerous locations made in the neighborhood of Gray's peak during the past summer. This one was located by Roberts Bros. & Co., and is a strong vein on the east slope of Gray's peak, and was taken up as a galena lode, the discoverers thinking the time would come when a mine of this kind would be valuable. To their surprise they found that the rock carried 36 ounces of silver, and the prospect is that it will be valuable for present working. The crevice is fully 7 ft wide, and the rock is evenly interspersed with mineral from wall to wall.

IDAHO.

Eureka Gulch.—Idaho *Messenger*, Nov. 3: The Atlanta has been worked more or less for the past 2 years, and is from 8 to 14 ft in width, and contains ruby and sulphides and sulphates of silver; the ore or pay streak in the vein varies from 2 to 6 ft in width; the value of which runs from 150 to 600 ozs per ton. The company are going to work 5 men on this mine during the coming winter, and have already laid in supplies to the amount of 9,000 lbs. and built 2 houses. The Idaho, situated about 300 ft easterly from the Atlanta, is a parallel vein, with similar qualities and formation; but in width ranges from 12 to 20 ft.

Beaver Gulch.—In this gulch, which is also on Beaver creek, are located a number of mines, one of which is the Ruby, of which the mammoth is an extension on the east. The Ruby is opened by surface cuts and 1 tunnel.

South Boise.—The Silver Shield and Baltic, belonging to the same company, are located across the main divide of the Sawtooth range on the North Fork, which is a tributary of Boise river on Bear creek.

Wood River Bullion.—Wood River *Miner*, Nov. 3: The Philadelphia Co.'s smelter at Ketchum, is turning out about 15 tons of bullion per day, which is shipped to Blackfoot as fast as teams can be procured. Last Thursday afternoon 66,000 lbs were shipped, and 44,000 lbs more were shipped Saturday morning, making a total of 110,000 lbs in less than 2 days. From Blackfoot the bullion is taken direct to the home office of the company in Philadelphia. After the first reaches there other lots should be received every two days. Nothing else is so convincing to the average mining operator as a pile of bullion bars, and nothing is more calculated to cause inquiry into the source of production than such a sight. These shipments of bullion will therefore do this section a great deal of good.

Sawtooth.—Cor. Wood River *Miner*, Nov. 3: Freighting has entirely ceased, and if the present stormy weather continues it will be impossible to finish the Columbia & Beaver stamp mill until spring. It is understood that Supt. Owen, after finishing the stamp mill for the Columbia & Beaver Co., is to erect a mill for the Mountain King and Vienna mines.

Work on the mines will be continued through the winter. Also, on the Pilgrim, Solace, Vienna and Mountain King. Mr. James Richardson has charge of the Pilgrim, Mr. Wallace of the Solace, Mr. Johnson of the Mountain King and Vienna mines. The snow is 3 ft deep in Smiley gulch, and business outside of the mines is entirely suspended for the season.

MONTANA.

Cora.—Butte *Miner*, Nov. 7: The shaft of the Cora is down some 215 ft, and the men are now engaged in retimbering with a view to beginning sinking deeper. Just at present no ore is being taken out.

Magna Charta.—Some 58 or 60 men are now busily at work in the Magna Charta, sinking below the 300 level, and taking out a great deal of ore. Yesterday Mr. Hall took Profs. Blake and Maynard through the mine.

The Alice.—The Alice is shut down for the purpose of overhauling the boilers, etc.

The Original Butte.—There are very slight changes in the condition of this mine since the last report. The hoisting works building is almost completed, and is now receiving a coat of paint. No sinking has been done for two weeks.

The Original.—Stoping is still going on in the east and west drifts at the 200 level, and the mine is looking well.

Dagnon.—Operations are progressing steadily and satisfactorily, with a good quality of ore and plenty of it. Stoping is being done between the 225 and 300 levels.

Morgan.—Operations were shut down yesterday for one day only, to adjust the spur wheel, which arrived on Friday from the house of Griffith & Wedge, Zanesville, Ohio. For several days past a full force has been working in the mine on the 200 and 300 levels. On the 400 and 500 levels nothing has been done on account of the water, which was lowered in the main shaft some 4 or 5 ft in the 24 hours ending yesterday morning. Stoping is proceeding regularly on the 200 and 300 levels, the regular quantity of ore, some 20 to 25 tons, being taken out daily.

NEW MEXICO.

Cow Spring District.—*Mining World*, Nov. 5: There are some excellent properties being developed in Cow Springs district. The veins are well defined in granite. On the surface they are only 12 inches wide, but at a depth of 25 ft, increase to a width of 3 ft. The ore is principally a sulphuret, and is high grade.

The Victoria mining district, two miles from Gage station, on the Southern Pacific, promises very rich. A number of St. Louis capitalists are largely interested in the mines. They have purchased a smelter which will be shipped to Victoria at once. Good claims command fair prices and many of the owners are not waiting to sell, but are going down on their prospects.

Part of the machinery for the 40-stamp mill to be built at the old Santa Rita copper mines is now on the ground and the balance on the road. The adobes and bricks, 100,000 of each have been contracted for to build additional furnaces, some 4 or 5 in number, which are already in course of construction. A force of some 200 men are now at work at these mines and the number will soon be increased to 400.

OREGON.

Mineral Resources.—*West Shore*, Nov. 3: The mineral resources of Jackson county, although its mines have been continually worked for 29 years, are far from being exhausted, and, indeed, it is only within three years that efficient hydraulic machinery has been introduced. The Sterling mine, owned by Capt. A. P. Yankony, of Portland, and Mr. Frank Enuis, the latter gentleman being superintendent, is without doubt, the most valuable placer mine in Oregon. It was opened several years ago at an outlay of $100,000; although its yield is not definitely known by the public, the property is valued by its fortunate owners at $2,000,000. The mine is situated on Sterling creek, about 8 miles south from Jacksonville, formerly one of the richest mining camps in the county. It is estimated that 50 years will be insufficient to work all the ground owned by the company. Another large hydraulic mine, paying handsomely, is owned by a Chinaman on Applegate creek; and still another owned by the Squaw Lake mining company on the same creek, will soon be in working order, and promises handsome dividends. The aggregate yield of golddust in Jackson county, since the discovery of the mines in 1852, is estimated by the best authorities at about $30,000,000, and it is said that by the aid of modern appliances and powerful machinery the mines will produce quite as well in the future.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Washington Drift G. M. Co., Nov. 5. Location, California. Capital stock, $500,000, in 50,000 shares. Directors: O. O. Francis, Abraham Halsey, C. W. Hendal, Ralph Plumb, L. R. Tuttle. The last named party owns 49,980 out of 50,000 shares of stock, the others 5 shares each.

Smith Manufacturing Co., Nov. 5. Object, to manufacture and sell agricultural implements, and to acquire patents and rights for improved machinery, and to manufacture and sell the same. Directors: Solon Pattee, W. J. Bevan, W. O. Richardson, Budd Smith and Daniel Buck. Capital stock, $600,000.

Redwood O. & S. M. Co., Nov. 3. Location, California. Capital stock, $5,000,000. Directors: Henry Raymond, M. A. Miller, Frederick Hotaling, S. S. Stambaugh, Elon Dewitt

Lost Treasure M. Co., Nov. 8. Location, Arizona. Capital stock, $10,000,000. Directors: William Sherman, William H. Lent, William Willis, George W. Osborne and George Congdon.

Polonias Placer M. Co. Nov. 8. Location, Los Angeles Co. Cal. Capital stock, $10,000,000. Directors: E. W. Skelton, Earl Bartlett, Theodore Reichert, H. Kelham and I. N. Thorne.

Oakland City Water Co., Nov. 8. Capital stock, $1,000,000, in 100,000 shares. Directors: W. R. Andrus, O. J. Dennison, J. A. Robinson, J. E. Bletben and Charles S. Kennedy. It is said that the supply of water is to be obtained from Summit House and ex-Mayor Bryant's ranch.

Camp O. & S. M. Co., Nov. 9. Location, California. Capital stock, $1,000,000. Directors: John Rebman, W. A. Beal, John A. Morris, E. A. Hatherton, J. T. Ohetwood.

"Grubstaking."

The Law about Verbal Grubstaking Agreements.

Judge Hallett, of the United States Circuit Court, in session at Denver on the 17th ult., rendered the following important decision:

Sarab E. Johnstone *vs.* Robinson, *et al.* Decision on final hearing. Hallett, J.

Sarah E. Johnstone, a married woman, and Mary A. and Ellen W., her infant children, filed a bill in the District Court of Arapahoe county against the unknown heirs of Charles Jones, to compel the conveyance of certain interests in mining property in the county of Summit. Afterwards George B. Robinson and the Robineon Con. mining company, who had acquired Jones' interest in the property, were made parties to the suit. On the death of Robinson, his heirs and perhaps his personal representatives were substituted for him as defendants, and the bill is now pending against those parties. The theory of tbe case, as advanced in the bill, is that Mr. Joncs, having been engaged with Mrs. Johnstone's husband in the San Juan country in the year 1877 in prospecting for mines, agreed with Mrs. Johnstone that if he should be brought out to Denver by ber or her husband, and kept bere during the ensuing winter, and furnished with an outfit for prospecting in the spring, that he would give to her and her children one-half the property which he should acquire during the summer, or that they should be interested with him in some partnership relation to the extent of one-half of what he should acquire during the summer.

It is alleged in the amended bill that all tbese things were done—that is to say, that Jones was brought to Denver, and kept during the winter, and furnisbed with the necessary outfit in the spring, and in the oourse of the summer that he acquired the property in which the plaiutiffs claim to have an interest, and which they wish to have decreed to them in this suit.

There is some evidence toshow that Jones was brought to Denver, pursuant to the agreement, and kept here during the winter by Mr. Johnstone. It may be assumed that the fact is proved, and as to the furnishing him with an outfit in the spring, there is testimony that some money was given to him at the time when he was about to start to Leadville, the amount of which is not shown; also some blankets and some clothing. It is not claimed that anything more was furnished him—provisions or tools, or animals, if any were necessary. As to that matter, then, it may be said that the proof is not full, doee not establish a compliance by the plaintiff, Mrs. Johnstoue or her husband, with the agreemeut.

Jonee went on to Leadville, and there, after sometbing of a spree, and idling around for some time, and making eimilar arrengements as to prospecting with at least two other parties, he went out in the interest of Mr. Robinson, or parties who were associated with Robinson, he himself being one of them, in an effort to discover mines. The mines in controversy here were discovered sometime during the summer, Jones baving in the discovery, by the terms of the agreement with Robinson and others, an interest of one-fourth, or eomething like that, in the locatious so made.

It is to secure one-half that interest so acquired by Jones under an agreement with these other parties, not with the plaintiff in this suit or any of them, but with other parties, that this suit is prosecuted. Jones died in the autumn of that year, and the bill was brought against his unknown heirs, these other parties becoming defendants afterwards.

Upon that statement of facts, I deem it only necessary to say that in my view the partnership relation, or if it be not called a partnership relation, but by some other name, the associabetween parties who may he engaged in prosecuting explorations in the public lands for mines, must exist at the time of the alleged discovery and location, in order to give to the parties associated an interest in the property. If it does not then exist, so that the person acting in the field, making the discovery aud the locatiou can be said to he acting for the otbers as well as himself, no interest can be acquired by those who are not personally present. Complainant's counsel seem to have felt the force of that rule, and tbey sought to establish the existence of this relation by Jones' admieeions msde by him at different times through the year to the effect that he expected to give some interest to Mrs. Johnstone and her children, or that tbey held some interest as discoverers. But that, I think, is not eufficient. Conceding that such admissions may have been made, and I think the evidence establishes that they were made, that is not sufficient to overcome the strong circumstances of the case. Mr. Jones had agreed with other parties, whose names I do not now recall, to go upon a prospecting expedition for them or to allow them to stand in iuterest with him. He wns a man of diesipation, and, ae ehown by the evidence here, in the habit of drinking about all tbe time when he could find anything to drink that would produce drunkenness, and for that reason I ehould say that not very much importance ehould be attached to his statements. But if we ehould give the greatest weight to them, the weight that would be attached to the declarations of a eober man of deliberate waye and habits of mind, I doubt whether it could be said that one having made one arrangement or agreement with certain parties to act witb them in eecuring mines, and afterwarde making another agreement witb other parties, and going apparently in pursuance of the last agreement, with the means furnished by his latest associates, could he said to be acting under and in pursuance of the firet agreement. I do not believe that tbat inference would be a fair one. If several persons associate themselves together by agreement to go out aud discover mines, and some of them furnish the meane of prosecuting the enterprise, as provieions and tools, and the like, and others go out and contribute their labor, and each party performs his pait of the agreement according to its terms, it is clear enough from the conduct of the parties—as well as their declarations that tbey nre acting in fullbillment of their contract and agreement, whatever it may be; but when this agreement is apparently abandoned, and eome new arrangement is made bstween new parties, and means are furnished hy some of them as arranged in the first instance, and others go out in the prosecution of the joint enterprise, any one would eay upon that circumstance alone, that they are acting under and in pursuance to the last agreement, and not the firet. And that is the situation of affaire here. I do not thiuk that it is open to discnssion even, that Mr. Jones, at the time he made these discoveries, was acting under hie arrangement with Mrs. Johnstone. He had abandoned that, as he had abandoned everything else apparently, within a day or two after it was made, and taken up with this new idea with the one who came to him last and furnished the necessary articles for prosecuting his enterprise; and it ie not to be inferred from that that what he did at that time is to bs taken as done in pursuance of the origiual agreement at all.

His acquisitions during this time, as ho got only a small interest in the property, must he taken to have been made for himself, and these plaintiffs were not interested in them at all; and whatever remedy they would have against him or his representatives for his breach of contract, they would have no right whatever to the property which he might acquire when acting under this new arrangement, this new agreement with Robinson and his associetes.

That is the strong reason in my mind which will enforce a decree for the defendante in this case.

This bill will bs dismissed and the defendants will recover their costs.

Bullion Camp.

The Bullion mine received some hose and other material for the hoisting works on Wednesday last. This mine, the Mayflower, Jay Gould, Eureka, and in fact all the minee now being worked in Bullion camp, are running all the hands that can be employed to advantage and rich ore is being piled on the dumps at a rate eurpassing any former time. Owing to the rise in freights there will be very little more ore shipped thie fall, the owners of the various mines preferring to let it accumulate on the dumps and wait for the low freight which can be secured next spring. It is rumored that the proprietors of a few of the largest producing mines in Bullion will club together and put in a big smelter at the month of Bullion gulch early next season. The site is a good one, being near the miues, only a short distsnce from timber and having good transportation facilities for its bullion over an almost dead level road all the way to Blackfoot nn the Utah & Northern railway, a distance of about 135 miles. The freight at present on ore from the mines in and about Bullion to the railroad is from $27 to $30 per ton and will probably increase as cold weather approaches and grezing along the road becomes poorer. Extensive preparations have been made for working the Bullion, Mayflower, Eureka, Jay Gould, Idahoan and O. K. mince during the winter. There are also a number of prospects being opened up in the vicinity which will be worked regardless of snow and cold. Some of these newly developed properties have very fine showings and a large amount of ore piled on the dump. We ehall look for an ontput of ore next epring from this group of mines many times greater than that of the entire season now drawing to a close. Other camps on the river tributary to Hailey are preparing for extensive work this winter and with the disappearance of enow we reasonably expect an increase in all branches of business far in excess of that enjoyed during the first few weeke of the boom which last spring was the making of three prosperous towns on Wood river.—*Wood River Miner.*

When a Location Can Be Relocated.—As many locators of claims are in douht as to when the annual assessment work must be done, the Gold Hill *News* furnishes the following important information: A miner making a location this year has until January 1, 1883, to perform the necessary labor, and the claim cannot he jumped and held before that time. It is untrue that the "jumping" eeason dates from the location of the claim, or, in other worde, that if a mine ie located on the 27th of October, 1881, it can he jumped on the 27th of October, 1882, if it has not received the assessment work. The law was made to protect the poor man. A miner, without means, locating a valuable claim on the 31st of next December, could hardly perform $100 worth of labor before the morniug of Jsnuary 1, 1882. The "jumper" muet wait until January 1, 1883.

The antimony minee near Lovelock etation, Nevada, belonging to Meesrs. Emmons & Jonee, are giving promiee.

Bisbee.

The Great Copper Camp of Arizona.

We take the following from the *Tombstone Epitaph*:

It ie with great pleasure that we are enabled to record another triumph among the mining industries of our county. A little less than a year ago the Neptune Mining Co. of Arizona filed its certificate of incorporation and immediately went to work developing its copper properties situated at Bisbee in the vicinity of the famous Copper Queen mine. After a careful investigation of the water supply at Bisbee the company decided to locate its smelting works upon the San Pedro river, aud purchased 600 acres of lend, being n part of the San Rafael grant. The land of the company extends upon both sidee of the river. On the weet side the town of Hereford wes laid out, and is bountifully supplied with fine spriugs several of which gush up from the soil, and at this point add materially to the body of water in the San Pedro. Those of our readere who have visited Bishee will remember Hereford as being one of the finest situations in the whole valley of the San Pedro.

About 500 yards from the east bank of the river the bottom lend terminates abruptly at the mesa, and upon the edge of the mesa the Neptune smelting worke are erected. The main building is 44 ft. by 34 ft., and consists of the engine-room and boiler-room. The engine is 60-horse power, and was built by Prescott & Scott, of San Francisco. The boiler is huilt in brick work, the bricks being made upon the land of the company about 250 yards from the emelter. To the right of the engine-room is the furnnce-room. This building ie 30x 30 ft. The furnace is a 30-ton sectional water-jacket, and was designed by August Rahl. Tracks are laid upon each side of the furnacs upon which a car is rnn and conveys the molds to the embankment from which the copper ie loaded. Immedistely bshind the furnace-room is the ore-room, being 30 by 30 ft., with n wide platform extending in the rear for the reception of ore. A 40-ton crusher is placed in the ore-room. This crusher is one of Blake's improved, and is one of the most powerful ever used. To the left of the ore-room is the sample-room, also containing a small Blake crusher. Behind the sample-room is the immense tank, containing 20,000 gnllons. The water is pumped into this tank by a powerful Cameron pump, and thence distributed to the works as required. The water is taken from a reservoir immediatcly at the foot of the mesa—being conveyed to this point by the gravel etrata underlying the bottom land from the river to the mesa. One hundred yards from the ore room is situated the office of the company, adjoining which is the assay office of the superintendent of the smelting works.

The Ores

Are hanled from the mines at Bisbee, 18 miles distant. The first run ie to be made at the smelter, on Saturday, and the dumping of the slag-pots will hereafter nightly illuminate Hereford, and become qnite a landmark to the traveler, and Mr. Herring puts down his run for the first 30 daye at a minimum of 300,000 lbs. of copper. As this company has never made any attempts at newspaper brag, we msy eafely credit the accomplishment of this resnlt. Some of the ores from the mines of the company are enormously rich, notably so the Uncle Sam and Neptune. While this company has not developed any great deposit like the Copper Queen, they have gone eteadily forward with tbeir development, and the manager reports 1,000 tons of ore now ready to be hauled to the furnace—not merely in sight, bnt on top of the ground, and that the indications of continuance are good. The reeulte already attained have required an enormous amonnt of labor and perseverance, and we wish the Neptune enterprise every snccess.

Burro Mountains as a Mining Camp.—From the earliest history attainahle through the archives of Mexico, the Burro mountaine have been looked npon as one of the richest silver mining camps in existence, and now comes the proof of their knowledge: First, the old mines owned by Givens & Irwiu, from which milling tests have run $164 per ton in silver, surrounded by a gronp of mines with assays rnnning high in silver, principally in chloridee; then the Silver Bell, owned by Crawford and others, carrying native silver and ohlorides running high in silver; aleo coppsr mines of a high quality of ore. Sand carbonates are found to the eastern part of the mountains, along a low range of hille and in the flats, eome 8 miles in length and 200 to 300 yards in width, assaye running as high ae $28 per ton. These carbonates are principally owned by Judge Ewing, and J. N. Moor, from Kansas City, who have commenced work to test the value of the claims; and they feel very sangnine they have gennine sand carbonstes. A new district has been laid out and called the Carson district, near Cherry Creek etation, and shows well ae far ae work has been done.—*New Southwest.*

The Nevada *Daily Transcript* saye: A good deal of prospecting is still being done at the old Meadow Lake diggings, and it is now reported that a ledge containing rich free milling ore has been found.

The Denver *Railway and Mining Gazette* highly compliments the mining machinery made by the Pacific Iron Worke of thie city. California mining machinery cannot be beaten.

San Francisco Fire Department.

The *Golden Gate*, a periodical published in Chicago devoted to insurance matters, and circulated among insurance people, in a recent issue publishes the following: "Nearly every large city claims to have the 'bset fire department in the world,' and the desire to make good the claim has led to a greater degree of excellence than wonld otherwise have been attained. Mr. C. F. Mullins, the able etatistician, has recently been gathering some figures bearing on the disputed question, and has exhibited the record of Boston, New York, St. Louis, Chicago and Philadelphia, as follows:

1877 TO 1880 INCLUSIVE.

	Number of Fires.	Insurance Involved.	Loss to Insurance Companies.	Per Cent of Loss to Insnce.
San Francisco...	1,259	$10,440,311	$ 1,242,242	11.90
Chicago	2,362	20,023,034	3,059,212	15.20
Boston.....	1,585	16,205,433	2,762,951	17.05
New York	4,676	66,051,218	11,861,829	17.70
Philadelphia....	3,080	25,940,142	4,611.132	17.79
St. Louis.....	1,207	11,475,177	3,774,177	32 85

"We have added San Francisco to the tables prepared by Mr. Mullins, to show that it heads the list of cities named in point of small ratio of insurance to loss involved. Fire Marshal Durkee, and Capt. White of the Fire Patrol of San Francisco are entitled to very great credit for the efficiency in their survice."

Chief Engineer, David Scannel shonld have been mentioned in the item and we add his name as he is head of the department which is so efficient.

Globe District.

Looking back over the last four years, we do not see a single marked success in mining in this district, but the Mack Morris. Since that mine became the property of the Mack Morris Co. Major Baldwin has been indefatigable in his efforts to make it a paying concern. It will eoon be a dividend producer. The secret ie that he brought the necessery knowledge combined with business ability of a higb order. Mejor Baldwin could not make ore wbere there was none, to be sure; but he can make what there is tell for all its worth. He has in his mine and mill as good men in their respective lines as the country prodnces; but be ie the presiding genine of the whole concern.

Thsre are a dozen prospecte in thie district that have a better showing tban the Mack Morrie had, with tbe eame development, that have gone by the board through incompetency and gouging.

Vale, the days of chicanery, of poverty stricken corporations, who burst up on the thresbold of success, of incompetency and puffery! All hail, the dsy of honest, intelligent and able management!

We spoke of the Carrie last week as a nonsnccess. It is measurably correct—the company have a good plant, and the True Blue mine ie said to givo a good ehowing of ore. If so the elements of snccess are thero.—*Silver Belt.*

That etannch advocate of American sbips, the *Nautical Gazette* relatee the following: One of the Monarch Line steamers came into this port a few weeke since, with a broken propeller wheel. To save time ehe was fitted np by the Morgan Iron Works with a spare one cast for the *Newport*, of the Ward Line, which was about 18 inches smaller than her original propeller. The owners intended to remove it ae soon as she reached Eogland, but to their surpriee, she mnde the run home in two days less time than she ever had done uuder the most favorable circumstances. It was concluded to let the "Yankee" wheel remain in position, and back she came at a rate of speed thet surprised everybody, and convinced her master, engineers and owners, that American mechanics did know eomething. We are satisfied that if we had such opportunity for practice in the building of large steamere ee the Clyde people have, our mechanics could produce craft that would outspeed even the famous *Arizona* and *Elbe*.

A New Mining District.—Reports bave come in from several different sources, that good qnartz had been struck near the headwatere of Man's creek, in Washington county. This week, Mr. Morris Kartzsr, whom we formerly knew in Baker City, Oregon, esme into our office and told us that he had been prospecting the past summer in the Man's Creek mountains. He eays that 22 lesds have been located in that eection. J. M. Packwood and Chas. Grim, Joseph and Robt. McCord, Chas. Huffman and Chaunoy Gone, Geo. Huffman and himself, have all located claims. Some of the claims carry a good deal of copper, hnt it ie principally eilver quartz. Tho veine are large and well defined, and many nf them run eeveral hnndred ouncee in silver. It is about 10 milee up the mountains from Snake river. M. H. Reed hae taken up a water right at the junction of Monroe and Man'e creek for a eawmill. There is plenty of timber and water eufficient to work the minee, and Mr. Kartzer thinke it will eoon develop into a good mining camp.—*Idaho Statesman.*

The Texas emelter of the California district, Arizona, is running out lead and eilver bullion. During the last 10 daye, 80,000 lbs. have been run, valued at $12,000. It will be ehipped direct to the lead works at Pittsburgh, Pa.

The Engineer.

Use of Glass for Engineering Construction.

A revolution in the common use of materials is promised by Mr. F. Siemens, who is at the present time making arrangements for the production in this country, on a large scale, says the London *Journal of Gas Lighting*, of his special make of toughened glass. This material has for some time been manufactured in Germany, and with the most satisfactory results; but it is believed that in England even greater facilities exist for its establishment as a regular industry. The method of manufacture is as simple as the reduction of iron-stone, and the annealing process, instead of being a separate and costly addition to the ordinary routine, as with the system of M. De la Baste, is as strikingly direct and economical as it is efficacious. The finished material may be made of any degree of fineness, and colored or enameled like ordinary glass, from which it differs chiefly in being practically unbreakable. Gas lamps glazed with Siemens' glass cannot be broken by the most violent storms, and pebbles thrown with force against panes will rebound harmlessly. It is said that the lamps along a promenade in Hamburg were regularly broken every winter by storms of sleet, until the tough glass was used, whereupon this destruction was no longer experienced. Other qualities of material are used for rail and water main pipes. These articles are much stronger than iron castings and imperishable and incorrodible. It is said that common castings, which are now procurable at prices which do not return the iron founder more than the barest profit or none at all, can be produced in Siemens' glass at about twice the figure, giving ample profit to the manufacturer. As the specific gravity of glass is only about one-third that of cast iron, the purchaser will be able to obtain glass articles at about 33% cheaper than similar goods in cast iron, as he will get, say, three pipes for the weight of one cast iron piece of main. It should be remarked that the Siemens' glass does not crumble to powder or break explosively when it is crushed, but cracks in precisely the same manner as cast iron.—*Industrial News.*

Survey of the Mokelumne.—C. D. Rhodes, civil engineer connected with the U. S. Engineer Corps on this coast, has, under instructions from Col. Mendell, completed an examination of the Mokelumne river from Woodbridge, the head of navigation, as declared by law, to deep water at the confluence of the Mokelumne and San Joaquin rivers, covering both forks of that stream. The principal obstructions found by Mr. Rhodes were above Staten island, or between the latter and Woodbridge. He made a sketch of the river, locating all the obstructions to navigation, snags, overhanging trees, etc., and reported the same to Col. Mendell, his superior officer. West of Staten island there is little to be done, and between that point and New Hope, the principal obstructions occur. Mr. Rhode's report is based on a thorough examination of the stream, and is officially submitted to Col. Mendell. What action will be taken in the premises remains to be seen. The improvement of the navigation of the San Joaquin and Mokelumne rivers is a matter that deeply concerns the people of this section. It is estimated that something over 70,000 tons of freight annually would be carried from that section were the Mokelumne in a navigable condition.

The East River Bridge.—That great bridge over East river from Brooklyn to New York will prove an expensive luxury. With the meager figures with which the trustees favor the public, the *Commercial Bulletin* has computed that the interest at rates from four to seven per cent. on the $13,799,900, which the stupendous structure has thus far cost, amounts in round numbers to $2,000 per day. The estimated cost 15 years ago, when it was commenced, was $3,000,000, the hight to be 200 ft. The hight has been reduced to 135 ft. and the cost increased to nearly five times the original estimate. The *Bulletin* does not think the bridge will ever pay. "The whole thing," it says, "is a job fastened upon the cities jointly by politicians and speculators."

From Rome to Naples.—The Italian Minister of Public Works has given orders for the surveying of a direct railroad line from Rome to Naples, as was proposed nine years ago by Danise. When the road is finished travelers can make the journey between the two cities in 3½ hours, or about half the time now necessary. Strategical considerations also have a bearing on the building of the line which will practically bring the important fortresses of Cannæ and Gaeta nearer each other.

The St. Gothard Tunnel.—It is believed that at last the engineers have mastered the quicksand formation in the St. Gotbard tunnel under Andermatt, by means of granite vaulting, and that the great work will be finished next month.

Electric Lighting is in successful operation on more than 60 steamers of the Mississippi river and its tributaries. It is believed to add much to the safety of that kind of traffic and traveling.

Useful Information.

New System of Glazing.

Rendle's patent system of glazing without putty or cement, which has been in practical use in England and the Eastern States for quite a while, promises to come into favor in Chicago and the West, whenever and wherever it is introduced. The conservatory curvilinear upon the premises of Mr. Wilbur F. Storey, on Grand boulevard, has been covered under the personal supervision of Mr. A. E. Rendle, the inventor, and the work is of a character that at once commends itself for excellence of finish and practical utility. In general terms, the special advantages the Rendle system claims over others may be summed up as follows:

The glass is placed in horizontal metallic grooves and fixed on wooden or iron purlins; the wood work and iron work completely covered and are not exposed to the influence of the atmosphere; if a pane of glass is broken, it can be replaced without trouble or expense, as it moves freely in the metal grooves; no putty or cement is used; it is economical, light, durable, and elegant; the patent grooves carry off the condensed steam on the inside as well as the water on the outside; the roof is very strong, yet as the panes are lapped one over the other and connected at the sides by only narrow strips of zinc, the entire surface has much the appearance of an unbroken sheet of glass; and last, and greatest of all, there is no breakage from expansion or contraction from heat or cold. Putties roofs can never be free from dampness by vibrations; yet roofs put on by this system are so elastic as to be almost entirely free from danger from that cause. The system has been quite generally adopted by English railroads for depots and stations, and is coming into use for the same purposes in America, as well as for conservatories, studios, exhibition halls, etc.

How to Furnish a Bed-Room.—A bed-room should impress the observer with the idea of a dainty cleanliness reigning supreme in every part of it, while the prevalence of cool, soothing tones of color suggest repose and rest. The paint might be delicate chocolate, the walls soft pea green; no color equals green for giving rest to the eyes, and in its paler tints it offers a pleasant sense of coolness during the most sultry days of summer, while they are free from the suspicion seen in many of the gray shades commonly used. Light colors make a room appear larger than the dark shades. Woodwork painted chocolate and cream walls, look well with bright blue furniture coverings and curtains, or maroon paint and citron wall with deep blue. A wall of a pale tone of blue and sage green woodwork will harmonize with furniture coverings bearing a design of autumn-tinted leaves. Stained boards are without doubt best for bed-rooms. A square of carpet covers the center, leaving three ft. clear all around the room. Dust invariably collects under furniture and chairs; dresses and drafts of air sweep it up into the corners; but the boards, being without covering, allow of its being easily taken up with a duster. Then, too, the carpet being simply laid down, there is no difficulty in the way of its being often shaken; no tacks have to be taken out or heavy wardrobes moved, so that there is no possible excuse for its being left down until the dust accumulates thickly.

To Harden Finishing Varnish.—A newly varnished carriage is liable to spot. To prevent this, some wash the carriage in clean, cold water applied with a sponge instead of using a hose; this will help harden the surface, and prevent it to some extent, from being injured by the mud or water getting splashed on the job. Never let mud dry on the surface and then wash off expecting to see no spots on the varnish. You will certainly be disappointed, and the only way to remedy the evil will be to have it revarnished. Soft water is better than hard water for the washing of carriages, as the lime which is in the hard water is very liable to injure the varnish.

Chinese White.—It is not wise to buy Chinese white in tubes. As we have often explained to correspondents, it may be kept moist in bottles, if a few drops of clean water are added each time any of the white is taken out. When the white rubs off your work it is a sign that there is a deficiency of mucilage, which is easily remedied by the use of a little gum Arabic.

Sugar in Milk and Butter.—Good sweet milk contains one-fourth more sugar than butter. This sugar turns to acid, and if this acid is too much developed before churning the coveted aroma is lost.

To Remove Ink from Furniture.—If ink has been spilled over rosewood or mahogany furniture, half a teaspoonful of oil of vitriol in a tablespoonful of water, applied with a feather, will quickly remove it.

Vegetable Germs in Arsenic.—Says the Boston *Journal of Chemistry*, the vegetation that sometimes forms in solutions of arsenic can be avoided, according to Perschne, by replacing one-fourth of the water with glycerine.

The Hair.—The microscope shows the hair to be like a coarse, round rasp, but with the teeth extremely irregular and ragged.

Railroad Signals.

The strange and dangerous dissimilarity of railway signals in this country has often been referred to, and the subject is brought forcibly to mind again by an interesting diagram in the *Travelers' Official Guide*, showing the whistle signals now in use upon about 200 lines. This indicates that, with the exception of the signal for backing, consisting of three short whistles, there is no signal in use having the same meaning on all roads, while no less than 40 different meanings are conveyed by several signals. According to this table, about 90% of the roads use one whistle for applying the brakes and about the same proportion use two short whistles for releasing brakes, while on others these sounds have exactly the opposite meaning. The signals for road crossings, sending out flagmen, recalling flagmen, calling for switchmen, calling attention to flag on engine and to railroad crossing, denoting that train has parted, calling for fuel, etc., differ widely; in fact, the code is based solely on the arbitrary fancy of the officer of each road. It is unnecessary to repeat that not only inconvenience, but often actual danger results from this dissimilarity of signaling, especially from the fact that railway men in this country are nomadic in their tendencies and wander from one road to another, so that the force of habit may lead to serious errors. All railway officers will agree as to the desirability of securing greater uniformity, but the trouble has been how to arrive at it. We are glad to observe that the new association of American railroad superintendents has appointed a committee "on train rules and signals," to report at the next meeting in April, and it may be that this association will furnish the means of bringing about the desired reform.—*Railway Press.*

Precious Metals Used in a Year.—The value of gold consumed by manufacturers during the last fiscal year was $10,000,000—more than $3,000,000 of which was in United States coin. The consumption of silver was equivalent to $300,000.

Ashes as a Fertilizer.—Ashes are, for many soils, a standard fertilizer. Places where a tree or brush heap has been burned often show the effects of the manuring for years. It is an old saying that "The land never forgets ashes."

Good Health.

The Diphtheria Plant.

In an address delivered a few weeks since before the Academy of Natural Science at Philadelphia, Prof. Horatio C. Wood announced as the result of recent investigations, that diphtheria was propagated "by a microscopic plant or fungus, existing in all human beings, especially in the mouth and throat, but lacking the power of reproduction until given increased vitality by those disordered conditions of the mucous membrane which attend sore throat when caused by a cold."

The investigations were made at the instance of the National Board of Health, and were extended over considerable time and in diverse localities. Prof. Wood proceeded to state that in all blood there are two kinds of corpuscles—the red or color giving, and white. By careful study and experiments, both in human beings and the the lower animals, it was found that this infinitesimal plant fastens upon the white corpuscles and multiplies its cells, altering their character, until with the interior destroyed they burst, and the plants, set loose in an irregular mass, separate and go off individually, to continue the destructive work on other corpuscles. Thus increased, they poison the blood, choke the vessels and are found in myriad numbers in the spleen and bone marrow, where the blood is manufactured. Prof. Wood's investigations show that the false membrane supposed to invariably indicate the presence of diphtheria, may be caused by ammonia, Spanish fly, or any other irritating influence in the throat, so that its presence is not infallible as indicating the existence of this disease. But in any case, the false membrane is built up by this parasitical plant, which grows and multiplies upon its inflamed surroundings, whatever may be its cause. It is when the plants grow strong enough to extend to the blood, either poisoning it themselves or carrying the poison with them, that diphtheria sets in. The little plant is exactly the same as found upon a coated tongue.

When Prof. Wood put plants such as found on a healthy tongue, in sterilized water, they failed to grow. On the contrary, plants from the throat or blood of persons affected with diphtheria multiplied rapidly. The practical result of the investigation pointed out, was the possibility that diphtheria, if existing theories prove good, may be prevented by artificial vaccination. In the case of splenic fever, caught from animals, which has been proved to originate in a somewhat similar plant, Pasteur has found that the plant, when exposed a sufficient time to the air, by the action of oxygen loses its poisonous character, and when then introduced into the system makes the animal sick, but is no longer fatal. The deduction is, that this diphtheric plant, scientifically known as "micrococci," may in time be cultivated so that when inoculated with it the system will no longer be subject to the disease in its fatal form.

Hurried Dinners.

It is a mistake to eat quickly. Mastication performed in haste must be imperfect even with the best of teeth, and due admixture of the salivary secretion with the food cannot take place. When a crude mass of inadequately crushed muscular fiber, or undivided solid material of any description, is thrown into the stomach, it acts as a mechanical irritant, and sets up a condition in the mucous membrane lining, that organ which greatly impedes, if it does not prevent, the process of digestion. When the practice of eating quickly and filling the stomach with unprepared food is habitual, the digestive organ is rendered incapable of performing its proper functions. Either a much larger quantity of food than would be necessary under natural conditions is required, or the system suffers from lack of nourishment. Those animals which were intended to feed hurriedly were either gifted with the power of rumination or provided with gizzards. Man is not so furnished, and it is fair to assume that he was intended to eat slowly. We must apologize for reminding our readers of facts so familiar; but we do this in the hope that any who may chance to have influence with the managers of large hotels where dinners *a la table d'hote* are in vogue will take measures to bring about a much needed reform in the manner in which these entertainments are conducted.

At the best and most frequented establishments in places of fashionable resort, where multitudes of health-seekers are wont to congregate, the hurried dinners are not only causes of annoyance, but actually go far to prevent the benefit which should be derived from a change. No sooner is one course served than another is introduced, without giving the guest time to digest or even to swallow the first. The eagerness to secure good dividends takes a particularly mischievous form when it piles food on the plate of a customer, and compels him to consume it breathlessly. The matter may seem a small one, but it is not so. Just as a man may go on for years with defective teeth, imperfectly masticating his food, and wondering why he suffers from indigestion, so a man may habitually live under an infliction of hurried dinners, and endure the consequent loss of health, without knowing why he is not well, or how easily the cause of his illness might be remedied.—*Lancet.*

Dread of Death.—Age, that lessens our enjoyment of life, increases our desire for living. Those dangers which, in the vigor of youth, we had learned to despise, assume new terrors as we grow old. Our caution increasing as our years increase, fear at last becomes the prevailing passion of the mind, and the small remainder of life is taken up in useless efforts to keep off our end, or provide for a continued existence. Whence, then, is this increased love of life which grows upon us as with our years? Whence comes it that we should make greater efforts to preserve our existence at a time when it becomes scarce worth the keeping? It is that Nature, attractive to the preservation of mankind, increases our wish to live, while she lessens our enjoyment; and, as she robs the senses of every pleasure, equips imagination in the spoil. Life would be insupportable to the old man who, loaded with infirmities, feared death no more than when in the vigor of manhood; the numberless calamities of decaying nature, and the consciousness of surviving every pleasure, would at once induce him with his own hand to terminate the scene of misery; but happily the contempt of death forsakes him at a time when it could only be prejudicial, and life acquires an imaginary value in proportion as its real value is no more.—*Goldsmith.*

A Natural Death.—Natural death is to die sweetly, without a sob, a struggle or a sigh. It is the result of a long life of uninterrupted health; of a long life of "temperance in all things," and such a death should be one of the ends and aims of every human being, so that we may not only live long, but in that long life, be able to do much for men and much for God. The love of life is a universal instinct; life is a duty; its peril or neglect a crime. We are placed on earth for a purpose; that purpose can be none other than to give us an opportunity of doing good to ourselves and others; and to be anxious to be "off duty" sooner than God wills, is no indication of true piety. The good man has one ruling, ever-present, desire, and that is to live as long on the earth as his Maker pleases, and while living, to do the utmost he can to benefit and bless mankind, and to accomplish a long, active and useful life. The study how to preserve and promote a high degree of bodily health is indispensable. And it seems to have been ordained by a Providence both kind and wise, as a reward of a temperate life, that such a life should be largely extended; that its decline should be as calm as a summer's evening; as gentle as the babe sleeps itself away on its mother's bosom.

Ancient Antipathy to Tobacco—April 18, 1621.—Sir William Stroud moved that he would have tobacco banished wholly out of the kingdom, and that it may not be brought in from any part nor used amongst us; and Sir Grey Palmes said that if tobacco be not banished it will overthrow 100,000 men in England; for now it is so common that he hath seen ploughmen take it as they are at plough.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—"Grubstaking;" A Conference of Miners and Farmers; Generous Gift to Science; A New Hoist; Weighing Ores, 313. Passing Events; Alaskan Mines; New Processes; The Debris Controversy; The Miners ask for an Injunction, 320. The Debris Committee, 321.

ILLUSTRATIONS.—The Pacific Prospecting Hoist, 313.

MECHANICAL PROGRESS.—Combined Anvil, Punch and Shears; Points about Lathes; The Life of a Car Wheel; Machine and Man Power in Production; A New Security Against Explosions; The American Society of Mechanical Engineers; Improved Emery Paper; Toughened Glass, 315.

SCIENTIFIC PROGRESS.—Chemistry in the Industries; Effect of Pressure on Seed Germination; The Camera for Detecting Forgeries; Cosmical Dust; The Survey of the Northwest; Ozone at the Paris Electrical Exhibition; Southern New Jersey Sinking; Extermination of Animals, 315.

THE ENGINEER.—Use of Glass for Engineering; Survey of the Mokelumne; The East River Bridge; From Rome to Naples, 319.

USEFUL INFORMATION.—New System of Glazing; Railroad Signals; How to Furnish a Bed-Room; To Harden Finishing Varnish, 319.

GOOD HEALTH.—The Diphtheria Plant; Hurried Dinners; Dread of Death; A Natural Death; Ancient Antipathy to Tobacco, 3 9.

MISCELLANEOUS.—Salmon River; Eureka Con.; The Eureka Tunnel; Candelaria; The Poison of Human Saliva, 314. "Grubstaking;" Bullion Camp; Elsbee; San Francisco Fire Department; Globe District, 318.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board. Notices of Assessments, Meeting and Dividends, 316.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana, Colorado, and New Mexico, 316-317.

Passing Events.

Probably the most important local event to record this week is the action taken with regard to enforcing the injunction on the hydraulic mines. The way this was done, was to order the Sheriff to cut off the water from the mines. The different companies where the Sheriff called and shut off the water, have brought suit and asked an injunction to prevent the action. The details we give in another column.

The committee of the Board of Trade of San Francisco, which visited the region affected by the debris, have made a full and complete report, which we give in another column. The report advises the building of dams to control the debris.

A notable event this week worthy of record is the gift of Charles Crocker, the railroad magnate, to the California Academy of Sciences. He gives $20,000 to the Academy to promote scientific research, the money to be spent in any branch to be selected by the Academy.

Several whaling vessels have come from the north and brought news of the relief ship *Rodgers*, but none of the *Jeanette*. The *Rodgers* has determined that Wrangell Land is only a small island.

As to mining news we give all that is of interest in other columns. From the northern regions we hear of work being stopped and roads blocked by the snow. The prospectors have all come in from the hills and are most of them in winter quarters.

No coal was ever found in San Diego county, though indications are that it will be some day, when thoroughly searched for.

Alaskan Mines.

We had a conversation the other day with Col. A. F. Williams, of Oakland, who has recently returned from a prospecting voyage in northern Alaska. From him we learn some interesting facts concerning the mining resources of the region. Col. Williams left here with a party, on a schooner, in May last. They went up through the Aleutian islands and through the Behring sea into Norton sound; but most of the time was spent in Golowin bay, on the north coast of Norton sound. Here are high rocky mountains, steep and abrupt, though there are large prairies next to the coast.

Col. Williams went with a whale boat 100 miles up the Fish river and sent a party overland. A land party also traversed the region, and quite an extent of country was located.

The principal location made was a galena lead or deposit. We have seen assay certificates by Prof. Price, giving the value at 83% and 85% lead and $121 and $161 silver. This is almost pure galena, that containing 86% lead.

Col. Williams says the Esquimaux utilize this by putting a piece in the bullet mold and running lead around it, to make bullets.

The country all about the region visited by Col. Williams and party is a very difficult one to prospect in, but this is not on account of the heavy timber, as most people suppose. This heavy timber is more prevalent in the southern part of the Territory. But there is a heavy coat of moss covering the whole face of the country, making it very hard to get about. In fact, it is a most villainous country to get about in. The moss is from one to two ft. thick, and the ground is more or less boggy, so that if one steps off the moss bed, he is apt to get into the bog. Ten or twelve miles is a good day's travel, so it is very hard to prospect.

There are belts of timber here and there, but the mountains are generally barren and free from brush and trees. Yet there is timber here and there, and plenty for fuel or mining purposes.

The country rock is mainly a micaceous slate; but no gold was found. The mountains seem to be of a white spar, which some suppose to be lime. There are great dikes of granite extending for miles and miles. No sulphurets of iron were found anywhere. There is plenty of mica in great scales and sheets.

The schooner was taken into Golowin bay and there anchored. The prospecting expedition went out from this point. They were in 64.30° N. and 163° W. Overland, they were not more than 50 miles from Kotzebue sound, in the Arctic.

Col. Williams judges this to be a good mineral region. The Esquimaux talked a good deal of the lead mines they knew of elsewhere. He has no doubt there is a good deal of mineral thereabouts.

The expedition left here on the 5th of May last, and met the ice on June 1st. They coasted around Norton sound some 200 miles. There are a couple of thousand Esquimaux camping around the shores of the sound. The party found them very generally willing to do anything asked of them. These natives packed the ore down to the vessel from the mine, some 15 tons being taken out for shipment.

When they return in the spring, horses will be taken up and sleds will be used for hauling ore. There is plenty of feed and hay along the coast.

They have an average of good weather in the summer, about as they have it in New York. August is wet but not cold. The first frost came on September 15th. In June the sun was out of sight about 2½ hours; it was broad daylight and no stars to be seen for two months. There are five good working months for surface work, and when once underground deep enough, the men can work all winter. There is timber within half a mile of the mine, so there is no difficulty in building houses to make the men comfortable. Col. Williams says the ore can be put down here in San Francisco at a cost not to exceed $50 per ton. It is unnecessary to reduce it at the mine, as there is over 1,600 lbs. of lead to the ton of ore.

Col. Williams had met some men who had come from 1,500 miles up the Yukon river. Up there they had been making from $10 to $15 per day to the hand in placer mines. They can only work about four months in the year. A little stern-wheel trading steamer now runs up the Yukon, to about 1,800 miles from the mouth. She only makes two trips a year. Her timber was got out here, and she was put together at St. Michaels.

There are only four white women in the Territory north of Kodiak. One lady is at St. Michaels, and she told Col. Williams that it was no colder there than at her native place, Portland, Maine. There is also a Chicago lady four miles from St. Michaels. There is one at Ounalaska, the port of entry, 2,100 miles from here, and one on the Island of St. Paul.

Col. Williams says there is an abundance of plumbago all through that country. His party is the first that ever visited that region. At the mine they sunk 20 ft., but did not get through the frost—the frozen ground. The heavy coat of moss seems to protect the ice, as ice is protected in sawdust and blankets. The tops of the mountains are free from the moss. The mosquitoes are innumerable and very annoying, fiercely contesting their rights to the country. They seem to breed in the ice.

When the party started away, they stopped with their vessel to get water, and while at anchor a severe gale drove the vessel ashore and wrecked her, she being a total loss. The Esquimaux took the party to St. Michaels in skin canoes, where some of them joined the revenue cutter *Corwin*, and were brought to this port.

New Processes.

Paragraphs about the new Hamilton process, now being tested in New York, are going the rounds of the press in every direction, and we scarcely pick up a paper but some reference to it is seen. We have before mentioned that the principle upon which these processes is based is no new thing, but is one that has been tried in a dozen different ways, none of which have been successful. Amalgamation by means of melted lead was known and practiced before the value of quicksilver in this respect was recognized. But in those days it was not necessary to figure things down to such fine points in working ore as it is now.

Not only has the principle of working ore in lead baths been known for a century or so, but in late years, quite recently in fact, the process has been revived and tried with improved appliances, but it has not been successful from an economical point of view. When, therefore, we are told that the method of applying the principle invented by Mr. Hamilton is to work ore for us for $1 per ton, we are doubtful; and when we are told in addition that a prominent Comstock operator has offered a million dollars for the right of one county alone in Nevada, the offer being promptly and absolutely rejected, we simply don't believe it. And when, moreover, they tell us that "500 orders have been received for this machine subject to the success of the present work when completed," we begin to think that perhaps the Hamilton process people may have some stock to sell or something of the kind. We do not know that they have, but should imagine so. We know to our cost out here, what absurd things people used to believe about new processes, and how easy it is to get people into them one way or another; and the processes generally get into the people pretty easy, too.

Now, when the Hamilton process accomplishes some good work on a large scale, say, in treating a thousand tons or so of ore, and receives the endorsement of competent metallurgists after careful examination, it will be time enough to believe we are to have ore worked for $1 a ton. But, until then, such assertions as we have referred to, serve to create a feeling that the whole thing is a humbug. Not that ore cannot be worked in that way, for we know it can; but that it can work ore for any such figures as stated. So far as we have noticed, no mining engineer or metallurgist of prominence has examined the process and given it as his opinion that ores can be worked by it for $1 per ton.

Thanksgiving Day.

Proclamation.

It has long been a pious custom of our people with the closing of the year to look back upon the blessings brought to them in the changing course of the seasons, and to return solemn thanks to the All-Giving Source from whom they flow; and although at this period, when the falling leaf admonishes us that the time of our solemn duty is at hand, our nation still lies in the shadow of a great bereavement, and the mourning which has filled our hearts finds sorrowful expression toward the God before whom we but lately bowed in grief and supplication; yet the countless benefits which have been showered upon us during the past 12 months call for our fervent gratitude, and make it fitting that we should rejoice with thankfulness that the Lord, in His infinite mercy, has most signally favored our country and its people. Peace without and prosperity within have been vouchsafed to us; no pestilence has visited our shores. The abundant privileges of freedom which our fathers left us, in their wisdom, are still our increasing heritage, and if, in parts of our vast domain, some affliction has visited our brethren in their forest homes, yet even this calamity has been tempered and in a manner sanctified by the generous compassion for the sufferers which has been called forth throughout our land. For all these things it is meet that the voice of the nation should go up to God in devout homage. Wherefore, I, Chester A. Arthur, President of the United States, do recommend that all people observe Thursday, the 24th day of November, as a day of national thanksgiving and prayer, by ceasing, so far as may be, from their secular labors, and meeting in their several places of worship, there to join in ascribing honor and praise to Almighty God, whose goodness has been so manifested in our history and in our lives, and offering earnest prayers that His bounties may continue to us and to our children.

In witness whereof, etc.

CHESTER A. ARTHUR.

By the President:
JAS. G. BLAINE, Secretary of State.

DURING the working of the gravel mines of Minnesota district, Sierra county, Cal., it was nothing unusual to find small bowlders of quartz containing from $1,000 to $5,000.

The Debris Controversy.

The miners or mining companies that lately recommenced work on their claims in defiance of the injunction placed upon them by Judge Keyser, have been proceeded upon for contempt of court. Judge Mayhew sitting in Keyser's Court at Marysville, issued orders to the Sheriff of Nevada county, directing him to shut off the water in all hydraulic mines already enjoined, and to post notices of injunctions on the Eureka Lake Co's. mines.

The Sheriff of Nevada county has complained serving the papers issued by Judge Mayhew in the case of Marysville against the enjoined hydraulic mines of the Yuba and tributaries. At the Milton mine, French Corral, he found no water running. At the Manzanita, owned by the same corporation, he shut the water off, and the Eureka mine's water was stopped. Mr. Searles returned from there, the others going to Moore's Flat and stopping the water of the Boston and China mines. The North Bloomfield was served on the return trip, and the Sheriff and his companions were treated with courtesy. No work was going on, the water, where it was found running, being perfectly clear. In each instance the Sheriff was warned by the representatives of the owners not to interfere with the property. He did not put in keepers. The miners will lose no time in endeavoring to obtain the right to resume operations. They are much exercised at their condition of enforced idleness.

Confidence is expressed that the mines will be in full blast again in a few days, with the sanction of the law. The Sheriff's bondsmen became a little alarmed, for the reason, it is generally believed, that the shutting off of the water will be declared an illegal act. Upon assurance from representatives of the mine owners that he would not be held responsible for the damage done they concluded to not withdraw.

In an interview, Hamilton Smith, Jr., Superintendent of the North Bloomfield mine, said: "The legal advisors of the miners in this city think that the order is illegal," was the answer. "You recollect that the Supreme Court, on an exparte hearing, decided that Judge Keyser was disqualified from trying the case of the city of Marysville against the Nevada county gravel mines. Judge Keyser then asked Judge Mayhew to bear the case, but instead of hearing the case as presented to Judge Keyser, he took the case up where Judge Keyser had stopped, and accepted all that had gone before to be legal. He then proceeded to order the enforcement of the Keyser injunction, not after hearing evidence in the case, but upon the plaintiff's affidavits that the miners had failed to obey the Keyser injunction. So, in effect, it is the Keyser injunction the Nevada county Sheriff is ordered to enforce, and not an injunction issued by Judge Mayhew."

Judge Dibble says: "That is a manner of serving an order or injunction heretofore unknown, or, at all events, undiscovered by the courts of this State."

As will be seen by what is given elsewhere, the miners have brought suit against the Sheriff for turning off the water.

The Miners Ask an Injunction.

On Wednesday the North Bloomfield, Eureka Lake and Yuba Canal, Meteor, Yuba Tunnel and China hydraulic mining companies began suit in the Superior Court of Nevada county to recover damages from Sheriff Tompkins for his having shut off the water in their mines by order of the Yuba County Superior Court, and to obtain an injunction against his further interference in the premises. The plaintiffs furnished $1,000 bonds in each case. Judge Caldwell issued the injunction, and it was served by the County Coroner. Report says that the mines will at once resume operations. The papers filed by the Eureka Lake Co. are fair samples of the others. After describing its status and property, this plaintiff avers that defendant, with force, shut off the water on the 8th inst., wrongfully damaging it in the sum of $500; that said ditches have a capacity of not less than 3,000 inches, miner's measurement, worth 15 cents per inch for 24 hours. The value of the mines is not less than $200,000; revenue yielded not less than $1,000 a day, and aggregate value of mines and ditches not less than $400,000. As a result of the water being continuously shut off, it is alleged that plaintiff will be deprived of the use of its water, the water entirely lost, the property depreciated in value and the revenues lost and destroyed, causing irreparable injury of a nature not susceptible of accurate estimate. It is further averred that the court calendar will not permit of the case being tried in several months, and that defendant is not pecuniarily able to respond in damages, wherefore plaintiff asks for a temporary injunction to restrain defendant, or his agents, from shutting off or interfering with the water, or preventing it from running down to the mining claims, or in any way trespassing or interfering with the working of said claims until a hearing upon its merit can be had, and that at a final hearing said writ be made perpetual.

THE *Times-Review* of Tuscarora district has ceased publication as a daily for the present, Tuscarora having gone down so much in the past few months, and there being no chance of its coming up until next spring.

The Debris Committee.

Tha committee to whom the important duty of visiting and inspecting the districts affected by the great debris question and of making a report thereon, with such suggestions as to a possible remedy or a compromise among the parties in interest, completed their labors and submitted their report, a copy of which is as follows:

The committee appointed by the citizens of San Francisco to investigate the subject of the injury done to agricultural lands by the debris from hydraulic mining, beg leave to report: That their investigation was made at the request of the Anti-Debris Association of the Sacramento valley. Their attention was called by that association specially to the condition of things existing on the Yuba, Bear and Feather rivers and the adjacent country, and their examination, therefore, has been confined entirely to that section of the State. They began their work at Marysville. There they inspected the Yuba and Feather rivers and the extensive levees intended for the protection of the city from the inundation of those rivers. Its condition is critical in the extreme. The bed of Yuba river along the front of the city has been filled up with mining debris to such depth that it is now above the general level of its streets. Formerly there was sufficient depth of water along its front to float steamers of considerable draft. The whole river to the opposite bank has been filled with white sand, and the only protection the city now has from annual inundation is by levees about 15 ft. in hight, constructed and maintained at an average annual rate of taxation for the last 10 years of five per cent. If the debris be allowed to flow into the river as in the past, it is certain that these levees will cease to afford further protection, and the ruin of the city will be inevitable. At no point of their examination did the committee witness a more striking illustration of the danger of an unchecked flow of the debris into the river channels. This debris consists of fine muddy particles held in suspension, which is known as "slickens," and coarse sand and gravel which rolls along the bottom of the rivers.

West Bank of Feather River.

The adjacent country along the west bank of the Feather river, in Sutter county, was next examined as far down as the town of Nicolaus. Along this line of 17 miles, levees of immense dimensions have been constructed, some of which have a width of 100 ft. at the base and 20 ft. at the top, and 15 ft. in hight, for the purpose of protecting that part of the country from inundation of the Feather river. The country in Sutter county lying to the west of the levee referred to, is a rich alluvial plain, much of which is under cultivation and covered with fine residences, barns and other improvements. Over this extended plain, on every hand, were the evidences of recent inundation of considerable depth. The committee was informed that this overflow was caused by the breaks in the Feather river levees during the winter floods of 1880–81.

East Bank of the Feather.

They next examined the east side of the Feather river in Yuba county, as far down as Bear river, and also the adjacent country. The evidences of inundation were on every side, and to a depth even greater than on the west side of the Feather river. At a point on the main road from Marysville to the Bear river bridge, the water marks on a barn standing on what is there termed high land, showed a depth of about five ft. of water during the winter of 1880–81. Along the lowlands on this bank of the Feather there was a deposit of white sand many feet in depth, totally destroying them. This was specially the case with a large part of the Miller ranch and the Mesick ranch, which, but a few years since, were under full cultivation in alfalfa, orchards and grain. These fine lands are now but sandy wastes. In much the same condition were the Lozier and the Plumas ranches. The houses on these latter ranches, although standing on high ground and at some distance from the river, showed evidence of an inundation last winter of from 5 to 10 ft. The whole condition of the country on this bank of the Feather river below the junction of the Yuba, was that of desolation.

South Side of Bear River.

The committee then crossed Bear river about a mile above its junction with Feather river, and followed up the southern side to within one mile of the town of Wheatland, at which point it is crossed by the California & Oregon railroad. Here again was seen even more deplorable evidences, not only of inundation, but of total destruction of lowlands by heavy deposits of white sand and debris. No language can convey an adequate idea of the scene presented at the Keyes and Brewer ranches. They were represented to have been among the finest lands of the State, under full cultivation, a few years since, and now they are sandy deserts. The residences have been raised from time to time some 10 ft. above their original base, to avoid the debris avalanche, but finally they have been entirely abandoned, as too unsafe for human habitation. At the railroad bridge across Bear river, near Wheatland, the story is repeated. The flood caused by the filling of the river bed has compelled the raising of the track not less than three times, amounting in the aggregate to 18 ft.

Vicinity of Oroville.

The committee next visited the Feather river at Oroville, and found a portion of its site subject to overflow chiefly from the discharge of debris from the hydraulic mines in the immediate vicinity. Here cause and effect were brought into close relation, and this point was examined rather as illustrating the general problem than as entering into that under their present consideration.

North Side of the Yuba.

The next line examined was the north side of the Yuba river, from Marysville to the point where the foothills begin, and where the Drainage Commissioners proposed to erect a retaining dam, but afterward the plan of the brush dam, some miles below, was substituted. From Marysville to this point the Yuba river has been leveed almost the whole distance at great cost, and numerous ranches along this bank have been totally buried in sand, among them the famous orchards of Briggs and Teegarden. Instead of a narrow and deep channel with bluff banks, as in former days, the river bed now is a wide, shallow sand plain, varying in width, from Marysville to this point, from one to two miles, entirely covered in the flood season by a swift current laden with further supplies of debris to be deposited at lower points of its own stream and in the Feather river, and on such lands as are low enough to receive them.

The Debris Deposit.

We learn from State Engineer Hall that the Feather river, at its junction with the Yuba, opposite the city of Marysville, has been filled from bank to bank, from 20 to 30 ft.; from 40 to 50 ft. at the site of the dam, eight miles above; from 100 to 120 ft. at Smartsville dumps, 13 miles above; and from 30 to 40 ft. at the forks of the river 8½ miles farther up; between these extreme points, he states that 100,000,000 cubic yards of heavy debris now rest above Marysville. It appears from the same authority that the aggregate amount of agricultural lands destroyed by debris in this section up to the year 1880, was 43,546 acres, to which may be added the damage caused during the winter of 1880–81.

The Brush Dam.

In their route up the Yuba, the committee examined the brush dam, which although built upon correct engineering plans was constructed in too great haste on account of the near approach of the rainy season, and was not completed in accordance with the plans, the northern 400 ft. being constructed of earth which was first, to give way when the storms began. The dam was about 10,000 ft. in length, of which about 1,400 ft. was washed out by the floods, the remaining portion withstood the storms and retained a large amount of debris. The committee are of the opinion that the repair of this dam is necessary for the safety of the country below it, and the cost is estimated by competent engineers at from $25,000 to $30,000.

Responsibility of the Hydraulic Mines.

The committee next entered on the examination of the cause of all the deplorable results they had witnessed on the plains below, the special point being the responsibility of the hydraulic mines therefor, and for that purpose examined the Yuba river, between Smartsville and North Bloomfield, and the principal mines which discharge their debris into it. These are characteristic of all the rest as to mode of work and discharge of debris.

The present system of hydraulic mining dates from the invention, in 1870, of the "Chief," a cannon-shaped machine, which rests on the ground and receives the terminal end of the pipe through which flows, within any given time, 50% more water than that furnished for the entire supply of the city of San Francisco. By aid of friction rollers, it can readily be turned in any direction and can be managed by a boy; it projects an 8 or 9-inch stream of water a distance of 300 to 400 ft., and with such enormous power as to readily move rocks weighing several tons. The machines are called Monitors and Little Giants, and several are used at times in a single mine, and in addition to running all day, are operated at night by aid of the electric light.

Extent of the Mining Industry.

The auriferous deposits, from 100 to 300 ft. in depth, are washed down to the bedrock, and the whole mass of slum, sand and smaller rock is discharged through sluices in greater or less quantity, directly or indirectly, into the channel of the Yuba river. The reservoirs from which this water is drawn are situated at the foot of the Sierra, and the ditches conducting it to the mines are in some instances 40 to 70 miles in length. Channels for the discharge of the debris have been excavated for miles in length through the bedrock. These works have cost very large sums of money, amounting to millions of dollars. The officers of the North Bloomfield, Milton, Eureka, Lake, American, Excelsior and South Yuba companies informed the committee that about $12,000,000 has been expended by them alone. The total capital invested in hydraulic mines is estimated to be $80,000,000, and it is represented that the amount of gold produced annually from the mines in this State is about one-eighth of the present aggregate product of the world.

Thrift in the Mining Regions.

The committee passed through many mining villages and towns, all showing evidences of thrift and prosperity. Comfortable schoolhouses were seen in every village, and the orchards and gardens surrounding the houses of the miners betokened a degree of comfort unusual for any laboring class. It was apparent that a considerable population, directly and indirectly, derives its support from the working of these mines; and their stoppage, even temporarily, would entail much hardship.

Where the Debris Comes From.

A careful examination of the hydraulic mines on this ridge satisfied the committee that the filling in of the Yuba river and the consequent inundation of the adjacent lands, is wholly due to the debris discharged by those mines into its upper channels; yet they saw enough to satisfy them that the hydraulic mines now being operated, are not entirely responsible for the damage done to the agricultural lands. Large quantities of debris were seen stored in the ravines at various places where no mining work has been done for many years past, and are swept down more or less by the heavy mountain rains of each year, helping to swell the sand tide upon the plains below.

Practicability of Dams.

The committee carefully examined a point on the Yuba river below the junction of all its forks and Dear creek, where, it was represented to them, a series of rock dams might be constructed, which would impound the debris of the hydraulic mines situated on those forks for many years to come. The problem is an engineering one, and they have the authority of Col. Mendell, of the United States Engineer Corps, and of Mr. Hall, the State Engineer, in saying that such dams are practicable, and will retain a very large proportion of the debris of those mines, and improve the condition of the river below.

In the report of Col. Mendell to the Engineer Department, under date of Feb. 20, 1880, he estimated the cost of a sufficient number of dams to impound 35,000,000 cubic yards of debris to be $222,025.

In the report of Engineer Hall, made in 1880, it is estimated that "there are 22 326,500 cubic yards of material washed annually into the canyons of the Yuba and its tributaries by the hydraulic mines; about 10% of this, or 2,332,650 cubic yards are believed to rest in the canyons above, by reason of the material being exceedingly large and heavy rocks; about 30% or 6,697,950 cubic yards are believed to be of such fine material that it will be carried out in suspension, and not be stopped by action of the dam, thus leaving 60% of the whole, or 13,395,900 cubic yards annually, of a character (sand and gravel) which will be deposited in the reservoir."

The Tule Lands as a Receptacle.

The committee are aware that it has been suggested that the tule lands south of Bear river and west of Feather river can be used as receptacles for the debris of the Bear and Yuba rivers. This would most probably help the Sacramento river, but falls short of solving the question in hand, for the safety of Marysville and the adjacent country requires that the mining debris be retained by proper dams as near the location of the hydraulic mines as practicable, so that the danger be met nearer its source.

The thousands of people engaged in agricultural pursuits and business occupations, whose property is in jeopardy, are demanding, in no uncertain tone, security against further damage. The construction and maintenance of their levees, unsafe barriers at best, would ere this have exhausted their means, but for the extreme fertility of their lands. They can stand but little more, and they must have relief or abandon their homes.

Mining and Agriculture.

Mining and agriculture are the two main arteries of our body politic, and neither can cease to pulsate without impairing its vitality. The whole State is to some extent a party to this contest. It cannot see without apprehension thousands of its citizens arrayed in two parties, each believing that the claims asserted by the other are wholly destructive of their respective rights and interests. Every effort must be made to end this dispute, and the committee appeals to good citizens of either side, to divest themselves of all extreme views and lend their influence to a fair settlement of this vexed and dangerous question. What is necessary, then, is for duly accredited representatives of the mining and agricultural interests to come together in a spirit of conciliation, and with a desire to adopt some plan by which a safe and speedy conclusion may be reached to protect the property and pursuits of both parties for all time to come. The committee recommends that security against further damage, and that speedily, must be given by the miner and accepted by the farmer, as the condition of his withdrawing further opposition to work on the mines.

How that security is to be guaranteed, whether by a stoppage of their work, and for what period such stoppage is to continue, are questions which can be adjusted only by a free conference such as alluded to. The committee sincerely trust that by such means a result satisfactory to both parties may be reached.

Magnitude of the Questions at Issue.

The committee would respectfully and earnestly represent that they have been deeply impressed with the magnitude and importance of the questions at issue, and the diversity of interests and the imperative necessity of an immediate concert of intelligent and scientific action of the parties in interest. The well-being and prosperity not only of the parties more directly interested, but of the State itself, require their speedy solution on some basis which will allow the prosecution, without conflict, of the mining and agricultural interests.

General Conclusions.

The committee therefore having that in view, would respectfully report as their conclusions:

First—That all property and property rights ought to be respected and protected.

Second—That the true interests of the State require the promotion of both the agricultural and mining interests.

Third—That the discharge of debris from the hydraulic and other mines into the river channels has been very destructive in its effect upon the agricultural lands and to the rivers and streams, and, if continued as at present conducted and operated, will be disastrous to the agricultural lands, and like a lava stream will blast and render sterile and barren that entire section of the country, blotting out its towns and cities, and rendering it a perfect "Sahara."

Fourth—That the hydraulic mining interests in which so much capital is invested, and which supports a very large, thrifty and intelligent class of our citizens, are of great importance and magnitude, and its encouragement is not alone desirable, but a duty, for its wants would tend to benefit and develop the very land which it will now destroy for want of concerted, scientific and judicious action being taken in the impounding of its debris.

Fifth—That dams be immediately constructed on the Yuba river, below the junction of Dear creek and at Degare Point; also, that the break in the brush dam on the Yuba river be at once repaired.

Sixth—That the entire cost of the construction, maintenance and repair of proper dams for the retention and storage of debris, should be borne by the mining interest.

Seventh—That the Federal Government should be urged to appropriate sufficient means to dredge and otherwise improve the navigation of the Sacramento and Feather rivers in the interest of commerce.

Eighth—That all litigation be suspended between the parties interested, as a further prosecution of vexatious and expensive proceedings cannot afford a remedy; but rather tend to exhaust the means and antagonize those whose best interests should cause them to co-operate intelligently and dispassionately, to obtain a remedy to protect the interests involved.

Ninth—That security against further damage is imperative, but whether that shall involve the stoppage of the mines during the construction of the dams is not our province, but that of the convention to decide.

Tenth—That in order to bring about a co-operation of the heretofore conflicting interests; to secure a fair, honorable and equitable adjustment of this matter; to adopt and carry out a speedy plan and remedy; to enlist the sympathy and support of the people of the State and its representatives, a convention be called in San Francisco, to convene on Thursday, the 17th day of November, 1881.

A Joint Conference Proposed.

That the Anti-Debris Association of Sacramento valley and the Mines Association each appoint 15 delegates to form said convention, duly authorized to act on this and all other subjects connected with their interests on the debris question, and if in their judgment they deem it advisable, select ten disinterested citizens of San Francisco, Oakland, or vicinity, as members thereof.

This convention will afford the farming and mining interests an opportunity to meet together and agree upon the details of a plan upon the basis proposed by the committee. If these interests desire a speedy and amicable adjustment of this question, they can by mutual concessions settle their differences in a prompt and efficient manner.

These views, the committee are aware, can have no further force than as the result of an impartial examination, and they are impressed with a belief that a contest in Court will be tedious, expensive, and fail to settle the question in time to give relief. In years later, if that course is relied upon, the parties interested will, on taking a retrospective view of the situation, and considering the amount expended with the damage which could have been prevented, conclude that the suggestion of the committee offered at this time would have been less expensive and more satisfactory in its results.

In conclusion, the committee desire to state that many facts connected with this subject and submitted, have not been referred to, it being the principal aim and desire of the committee to conduct the examination and to report thereon, with the view of harmonizing, as far as practicable, the feeling naturally engendered on both sides, and endeavor to bring about a concert of action for mutual protection in the future. The committee were impressed with the opinion that an intelligent consideration of this subject by representatives of the parties interested, who possess an intimate knowledge of the evils and the imperative necessity for a remedy, would tend to a practical, peaceful and beneficial solution, alike creditable to them and to the people whom they will represent.

SAN DIEGO COUNTY mines need financial aid.

"THE $1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

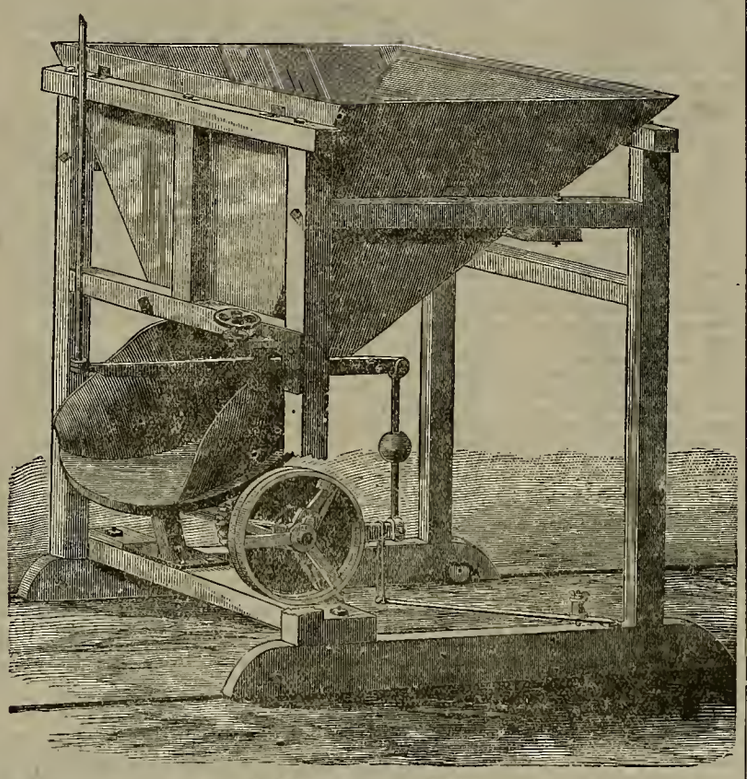
OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.



The Challenge Ore Feeders are now in Use in the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Uintah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse"

The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted.

The "Silver King," Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sols" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

JOSHUA HENDY, Agent,

Machine Works, 49 and 51 Fremont Street, San Francisco.

Manufacturer of Quartz, Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRAHAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING from the Akron Iron Company, of Akron, Ohio.

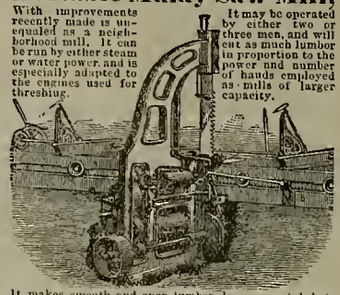
Goodyear Rubber Co. R. H. PEASE JR. S. M. RUNYON AGENTS. SAN FRANCISCO.

Portable Mulay Saw Mill,

With improvements recently made is unequaled as a neighborhood mill. It can be run by either steam or water power, and is especially adapted to the engines used for threshing.



It may be operated by either two or three men, and will cut as much lumber in proportion to the power and number of hands employed as mills of larger capacity.

It makes smooth and even lumber, leaves no stubshot, and will cut any sized log up to four feet in diameter.

It may be transported from one locality to another and re-erected ready for sawing in from two to three days, and can be made profitable in localities where there is not sufficient timber to justify the erection of a large mill. Send for descriptive circular, price, etc., to CHANDLER & TAYLOR, Indianapolis, Indiana.

We also build the heavy Standard Circular Saw Mill, with either one or two saws as well as the Pony Circular Saw Mill that is capable of being run with light power. We also build Stationary Engines of varied capacity; also, portable Threshing Engines.

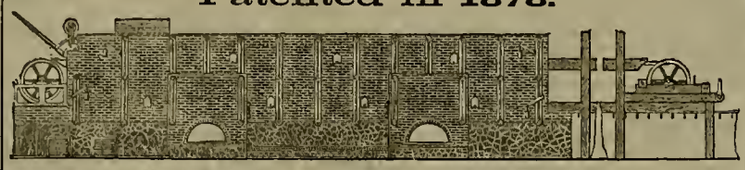
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand
SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteeian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.
SHEET IRON PIPE.

THE O'HARRA
CHLORIDIZING FURNACE.
Patented in 1878.



SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.
BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

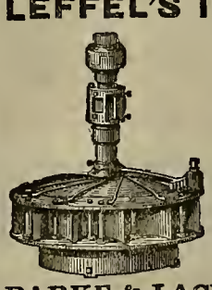
An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.
A cheap Furnace to build and to run.
The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.
At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.
At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61¼.
Lewis Chalmers, of the Isabella O. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenical sulphurate of silver up to from 84% to 95% of the assay.

SEND FOR DESCRIPTIVE CIRCULAR TO
WHITNEY, YEASEY & CO.,
Carson City, Nevada.
Agents for San Francisco, KUSTEL & CO., 318 Pine Street.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill. It requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies. Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞ Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.



PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

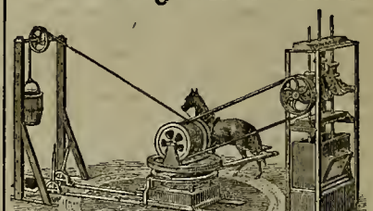
New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 252 Market St., S. F.

FOR THE WEEK ENDING NOVEMBER 1, 1881.

248,835.—SEAL PADLOCK—A. M. Adams, S. F.
248,906.—HORSE-POWER—C H. Laker, S. F.
248,909.—FENCE BARE—W. W. Butler, Boise City, I. T.
248,911.—METALLIC LATH—P. Caduc, S. F.
249,062.—SHIRT—L. Lemos, S. F.
248,938.—HYDRAULIC DERRICK—O. M. Loveridge, Weaverville, Cal.
248,890.—TYPE WRITER—A. G. Sbannon, Santa Rosa, Cal.
248,068.—STAMP MILL.—J. M. McFarland, Virginia City, Nev.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

METALLIC LATH.—Philip Caduc, S. F. Dated Nov. 1, 1881. No.248,911. This invention relates to improvements in that class of laths known as metallic laths, and which are intended to take the place of wooden lathing. The improvements consist in a peculiar formation and construction of the lath, by which the inventor is enabled to produce a more complete and firmer bond for the mortar, while the lath itself is made very firm and stiff, with no tendency to bend or lose its form from the weight of the mortar. This sheet metal lath has the edges turned inward to an acute angle, while the central portion is formed into a projecting double incline, said double inclined faces having perforations or slots made opposite to each other, so that the mortar shall pass through and lock.

HYDRAULIC DERRICK.—O. M. Loveridge, Weaverville, Trinity county, Cal. Dated Nov. 1, 1880. No. 248,938. This invention relates to a novel combination of a hydraulic water wheel, with certain intermediate glazing, so that the direct force of a stream of water may be brought to act upon the wheel, to drive the hoisting drum at a slow or fast speed. The apparatus is constructed by metallic levers, and from the position of the wheel is entirely protected from wet, while the derrick may be turned in any direction. By the peculiar construction the inventor provides a combination of a derrick and a force wheel, which is easily handled, and the wheel is entirely out of the way beneath the platform, so as not to throw water to splash the operator or machinery.

The Veterans' Home.

A commendable movement is now in progress to raise funds to establish a Veterans' Home, where the helpless survivors of the war may be housed and cared for during the remaining days of their pilgrimage. It is proposed to locate the Home upon a farm where it may be made self-sustaining after the land and buildings are paid for. The project will commend itself to patriotic men in all parts of the State, and we doubt not all who can contribute to the cause will be glad to do so. The following circular will explain the need for the Home and what is required to secure it:

The Executive Committee of the Veterans' Home Association beg to present the following:

1st. We have the names and postoffice addresses of about 7,000 veteran soldiers and sailors resident in California, who served under our country's flag in past wars; and we know there are many more on the Pacific coast

2d. One hundred of these are in public almshouses of California, and a much larger number, by reason of old age and infirmities, are being surely drawn to them.

3d. Patriotism, humanity, and even public interest demand that these suffering relics of our country's defenders should be provided with a home where they may live in decency and respect, and, dying, escape burial in paupers' graves.

4th. Many States of the Union have built such homes for their disabled soldiers and sailors, and our remoteness from the national center makes it necessary that there should be such a home on this coast. Our Veteran Home Association now appeals to the generous and patriotic people of California to furnish money to buy an ample tract of productive land, enough to establish it on a self-sustaining basis.

5th. Sixty thousand dollars will do to start it and give a home to the maimed and helpless, while those who cannot obtain employment or do full work, will there have shelter, food, books, newspapers and companionship, by the aid of their own labor, and such help as may be reasonably expected from the Federal and State Governments.

W. S. ROSECRANS,
Chairman of Executive Committee.
Headquarters, Nucleus Building, S. F.

NINETY cars of freight pass daily over the Southern Pacific eastward. To do this work between Los Angeles and Yuma, 24 large and powerful locomotives are employed. On the ascent towards Colton from Los Angeles two locomotives are employed to each train. From Colton to and beyond ths San Gorgonio summit an extra locomotive is required. These heavy trains are largely loaded with merchandise and Los Angeles produce.

THE Spanish government has decided to release all political prisoners.

Brief Mining Notes.

Two of the principal mines of Tuscarora have closed down, and others will follow. Not a stamp will be dropped in the camp before next spring.

IT appears that there is a continuous mineral belt running through Nevada, Cooper and Taylor districts, Nevada, a distance of fully 15 miles.

ATTENTION is being more freely given to gold quartz mining in California, now that the Comstock does not attract all the attention of mining men.

A CORRESPONDENT of the Eureka *Sentinel* says it requires two summers to get the machinery in for one 20-stamp mill into the Sawtooth region, Idaho.

THERE are numbers of quartz ledges in this State, which would pay handsome profits if capitalists would take hold of them and help the owners put them in shape for profitable work.

The Sawtooth range is believed to be the best part of the Wood River country. On the Sawtooth they have free milling ore and a good deal of it. But that part of the district is extremely rough in the winter.

SUPERINTENDENT GOULD is still bothered and perplexed by the sickness of the men at Mendha mine, Nevada. The mine is shallow and there are two shafts which afford good ventilation, and yet the miners give out. The most of them say they are leaded.

Two men, one day recently, took out $2,000 worth of ore from the Monitor mine, Taylor district, Nevada. This is a stand-off for that $1,000 worth of ore taken out of the Eureka tunnel one day, by one miner, that the *Sentinel* wanted to see matched elsewhere.

WELLS, FARGO & Co's. bullion shipments from Silver Reef, Utah, for the month of October aggregated $83,690.41. The outlook of the sandstone district was never brighter, and the yield for the ensuing season promises to be the largest since its discovery.

ABOUT 200,000 ounces fine silver was turned into the San Francisco Mint on the 4th, for account of the Government, at $1.13 per ounce, which was the price offered that day for lots over the counter. The above amount was awarded at Washington, the Nevada bank getting 110,000 ounces.

THE Boston mill company have bought the Stonewall mine, Tombstone, for $100,000. This purchase gives assurance that the Boston mill, that heretofore has had to depend entirely upon custom work, will hereafter be kept running at its full capacity and thus give an additional output of $100,000 or more per month.

PROSPECTORS have been showing specimens of rich gold rock which they claim to have found near Hailey, in the Wood River country. It probably came from California. The *Miner* says: This is a silver bearing region and though a sprinkling of gold is found in some localities, we have yet to learn of anything like a gold mine hereabouts.

THE Amador *Sentinel* asks the Sacramento *Bee* if it considers one of the miners' rights is "permission to come down from the mountains and work 17 hours a day in your 1,000 acre grain field, by the side of a Chinaman and for Chinese wages? That is one of the principal 'rights' enjoyed by the farm laborer of the Sacramento valley."

DON'T be fooled by the exhibition of a fine piece of rock nor take stock in any miner or prospector who offers to show you his claim, and promises to give you an extension for a certain amount of cash. He may be honest in his intentions; but if he is, he will take you to his claim without charge, save, perhaps, enough to defray actual expenses, and sell his property on its merits.

THE Tuscarora *Times-Review* says: From several years' experience in isolated mining districts as publisher and proprietor of newspapers, we have learned that in most prosperous times, during the winter season, the business is unprofitable, and further, that the irregularity of the mails, and the general inaction of our home people, creates such a dearth of news, that the labor of filling the columns of a daily is not only laborious, but, when performed, is very unsatisfactory.

PAN WORK.—The Ward *Reflex* says the Monitor mill is in good running order, and barring unforeseen accidents, will not shut down again until the water freezes up. It now puts through between seven and eight tons daily. It being a water mill and running under small expense, makes it a paying institution. The estimated cost of working the ores is between $5 and $6 per ton. Experiments have been going on for some time, and it having been ascertained that the ore can be worked up to as high a per cent. by running four hours in the pans as by six and eight hours, it has been decided to put in a 50 screen instead of the 60, and work 400 instead of 200 tons of ore a month. This will be done as soon as another pan can be put in, which will not be later than two weeks at the outside.

THE Boston *Post* says that the man who has been speculating in Confederate bonds, explains that he did so because he wanted to tackle something that was a little safer than the average mining stock.

News in Brief.

ANGLO-FRENCH intervention in Egyptian affairs is threatened.

GEN. SHERMAN advocates an increase in the army of about 20%.

A FAMINE is feared in northern Russia, owing to a failure of crops.

FIVE thousand lives were lost by the recent floods in Spanish Honduras.

BY a fearful typhoon in western Tonquin, China, 6,000 Christians are ruined.

A STATUE of Lord Byron has been unveiled at Missolonghi, Greece, where he died.

NEARLY all the mills on the Carson river are likely to be in operation this winter.

A DANISH naval officer is about to begin a search for the Arctic steamer, *Jeannette*.

THE Turkish government is preparing to chastise the rebellious tribes of southern Arabia.

PHILIP E. SULLIVAN, one of the Iron Mountain train robbers, has died in prison of homesickness.

ACORNS in Redding are selling for more per bushel than wheat in Modoc county. The former are worth 75 cents per bushel, while the latter only brings 50 cents.

ADVICES from Mecca, to the end of October, report that the number of cases of cholera averaged 15 daily. The number of pilgrims in that city was 100,000.

Removal of Dewey & Co.'s Patent Agency and Newspaper Offices.

October 29th the patent agency and newspaper offices of Dewey & Co., were removed to the northeast corner of Front and Market Sts., occupying a large space on the upper floor, where we have spacious and pleasant rooms for the accomodation of our increasing business. Our apartments will have two entrances as shown in the following engraving: Our stairway, No. 252 Market St., and our elevator, No. 12 Front St.

☞ Take the Elevator at No. 12 Front St.

Visitors will find it better to step around the corner from Market St., to the elevator rather than ascend the stairs. Old and new friends are cordially invited to give us an early call in our new quarters.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOOKSELLERS, STATIONERS, ETC.—Messrs. Payot, Upham & Co., No. 204 Sansome Street, are one of the oldest, most enterprising and reliable firms in the book and stationery trade in San Francisco. Scientific, industrial and foreign publications are a specialty with them. They are also noted for their first quality of blank book and fine stationery line of goods.

THE advertisement of F. Mansell & Co. in another column shows that they have moved to 434 Pine street, opposite their old stand. For ornamental, sign, and glass work, gold block letters, etc., this firm bears an excellent reputation in San Francisco, where it has been long established. We ourselves have patronized Mr. Mansell for many years.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry O. Hanks, State Mineralogist.

ANNUAL STATISTICIAN of 1881.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 816 California st. Price, $4.

1851. 1881.
DEPUTY U. S. MINERAL SURVEYOR.

Sign and Ornamental Painters,
NO. 434 PINE ST., SAN FRANCISCO,
(Opposite their old stand.)
Fancy Glass Work, Gold Block Letters, Etc.

THE FRANKLIN GIRDER!

BY FAR THE MOST ECONOMICAL OF ANY CONSTRUCTION MADE.

This new and economical Girder for Buildings and Bridges, made of any desired length and to sustain any required load, and guaranteed to be fully up to the sustaining capacity represented. The price of these Girders is ABOUT ONE-HALF the price of those of same length and same sustaining capacity in common use in this city. The value of this invention has been most favorably commented on in full by most of the scientific press of this country, as the SCIENTIFIC PRESS, *Scientific American*, *Railway Review*, *The California Architect and Building Review*, *The American Architect and Builder*. A Girder 25 feet long, made for 17-inch wall, with about 2 feet of brick wall on it, is now in front of premises 231 First St., above Shot Tower. This Girder held on the top of the brick wall now on it, 117 Tons and 1,741 Pounds of Railroad Iron, at the Pacific Rolling Mills, piled directly over and between supports, and it would have held, in the opinion of experts 200 tons, as the deflection was not a quarter of an inch below the true arc. The foundation on which the Girder rested, settled 7 inches, so that the loading had to be stopped at the above weight.

The Price of these Girders, 25 feet Long, to Sustain 100 Tons as a Safe Distributed Load, $200.

THOSE IN COMMON USE NOW IN USE IN THIS CITY COST NOT LESS THAN $400.

And other sizes in like proportion. Every Girder guaranteed to sustain the load as a safe one; the breaking load being three times greater.

Prices for any Size and Sustaining Capacity given on Application.

P. H. JACKSON & CO., Makers,
2 California Street, and 231 First Street, San Francisco, Cal.

P. H. JACKSON,
Civil Engineer.

CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francisco

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from $2.50 upwards
R. HUGHES, Proprietor.
At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

It surpasses all other Grates for convenience and economy in use of fuel. No stove complete without one. It will pay for itself in one week. Manufactured by
KEARNS & CALDWELL, 901 Shotwell St., S. F

INGERSOLL
ECLIPSE ROCK DRILLS

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing

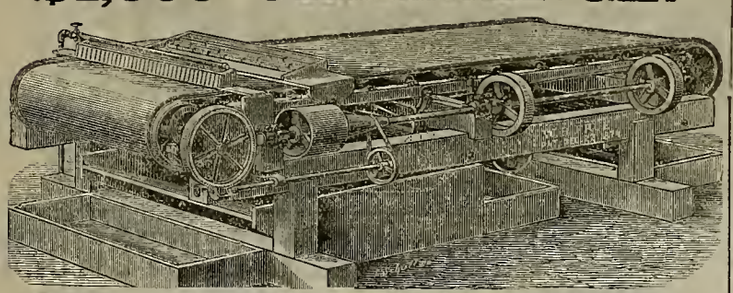
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞ A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞ Triple Force Caps and all Grades of Fuse.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, NOVEMBER 19, 1881.

VOLUME XLIII Number 21

Wood-Working Machinery.

Messrs. Parke & Lacy, of 21 and 23 Fremont street, have recently added to the branches of business they represent, by keeping on stock a large amount of wood-working machinery, saw mills, etc. For saw mills, etc., there is quite a demand in many directions, even in Mexico. This is due to the rapid growth of the railroad systems of the country and the increase of our mining area. Many mining companies find it is more profitable to purchase the saw mill machinery and get out their own lumber than it is to purchase lumber, when the latter has to be transported any distance.

Messrs. Parke & Lacy are now agents for this coast for Witherby, Rugg & Richardson's wood-working machinery, and keep in stock a full line of these goods.

We illustrate on this page a machine made by this firm especially to meet the requirements of this coast. It is called the California planing, tonguing and grooving machine.

This machine has been perfected with great care, and is built from new patterns of the most approved styles, with Burleigh's patent expansion feed gear links; also improved weighted feed rolls, self-adjustable to the variations in thickness of lumber. The rolls are weighted so that the lumber passes through before it reaches the cutter head, giving at all times an equal pressure in all the irregularities of the lumber, which cannot be obtained otherwise.

It has four six-inch feed rolls; the cutter head is six inches in diameter, carries three cutters, is made of solid cast steel, running in the best of babbit lined patent self-oiling boxes. All the gears are protected by substantial covers, thereby preventing breakages or accidents. It will plane, tongue and groove 14 inches wide. Will plane 24 inches wide and 5 inches thick when the matcher heads are off. The matcher head is moved by a crank both on the end and side of the machine, with an index to gauge the width and thickness of the board. Tight and loose pulleys, 14 inches diameter, 6-inch face, and should make 750 revolutions per minute. Length of belts, 37 ft. of 4-inch, for upper cylinder; 18 8 12 ft. of 4 inch, for under cylinder; 35 9 12 ft. of 3-inch, for matchers; 14 6 12 ft. of 3 inch, for feed. Power required to drive planer, 12-horse.

California Silk Culture Association.—Hon. Irving M. Scott will deliver a lecture on India at the Mercantile Library hall on Saturday evening, Nov. 19, for the benefit of the California Silk Culture Association. The ability of the lecturer is widely recognized, and the object for which he will speak is in every way worthy of generous encouragement. As most of our readers well know already, the California Silk Culture Association is composed of a group of public spirited ladies who are laboring to promote the silk industry in California, and they have already attained most satisfactory results. We trust they will be aided onward by a full house at Mr. Scott's lecture. This society held its regular monthly meeting at the Academy of Sciences, on Thursday evening last. Several interesting papers were read, treating upon the progress and importance of silk culture and silk manufacture in this country. In order to encourage the introduction of silk culture, the rearing of worms and the production of eggs, the society last year distributed quite a number of eggs to different parties throughout the State, and it proposes doing the same the coming season. Eggs will be furnished gratuitously to such as are living in localities favorable for such culture, and are unable to pay for the same. Purchases of eggs will also be made of such persons as have healthy ones for sale of their own raising. Applications may be made to Mrs. Marwedell, 1711 Van Ness avenue. Mrs. Thomas Varney, Mrs. P. H. Barclay, Mrs. B. F. Holbrook and Mrs. Laura De Force Gordon were elected members of the association.

Reports received at the Mint Bureau, in reply to circulars recently forwarded by Director Burchard show that during the fiscal year ended June 30, 1881, the value of gold consumed by manufactures aggregated about $10,000 000. More than $3,000,000 of this amount was in United States coin. The reported consumption of silver during the same period was equivalent to $3,000,000.

The mineral belt at Butte, Mon., is over three miles long from north to south, and some two miles wide from east to west. The course of the veins is east and west, and the dip is generally to the south. The ledges are from 6 inches to 15 ft. in width. The ore is base, and must be roasted or smelted.

Sheaves for Hoisting Works.

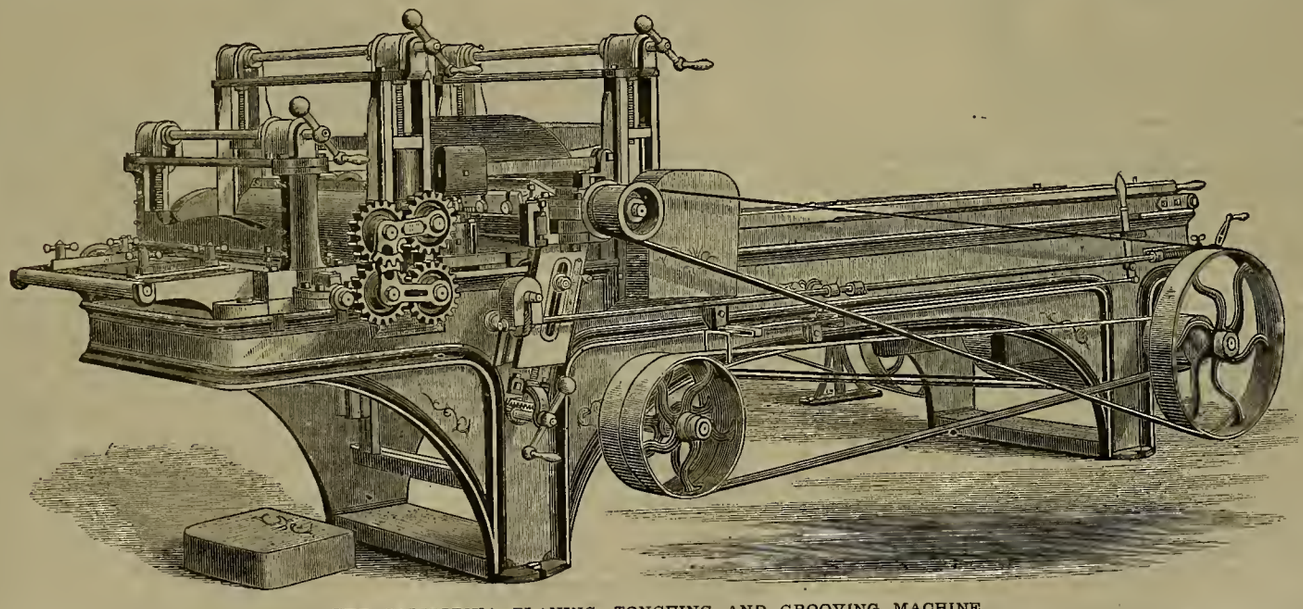
In discussing the question of the mechanical engineering of mines, Mr. C. M. Percy, a member of the Institute of Mechanical Engineers, and author of "Winding and Overwinding," etc., calls attention, in a recent lecture, to the care which should be exercised in constructing head gears to proportion the pulley bearings correctly. The pulley axle should be so strong as to make accident impossible, but we ought to have strength, and also such an axle as will give the least amount of frictional resistance.

In view of Mr. Percy's wide experience, and his practical knowledge on this subject, his conclusions will be of interest to our miners and foundrymen. We must bear in mind that all the load rests upon the bearings of the axle, and that the friction of bearings increases with the load and also with the distance traveled. We cannot help the load, but we can reduce the distance which the bearings travel, or rather are traveled upon, in two ways—namely: First, by keeping the pulley as large as possible, and, second, by keeping the journals as small as possible. This can be made clear by a simple illustration. Suppose a head gear pulley, seven ft. in diameter, and a journal, eight inches in diameter, for a pit 300 yards deep. The pulley will revolve 40 times each winding, and the distance traveled by the journal upon its bearing will be 85 ft. each winding.

Suppose, for the same pit, a pulley 14 ft. diameter and a journal 4 inches diameter. In this case, the number of revolutions will be 20½, and the distance traveled by the journal upon its bearings 21¼ ft., being only one-fourth of the amount in the previous result. A headgear pulley axle made of the class of wrought iron to which axles are entitled, in which a bar 1 inch square and 12 inches between the supports, will have a breaking stress not less than 3,500 lbs., does not need great dimensions to make it strong. An axle, with journals 4 inches diameter and measuring 2 ft. inside the journals, will have an ultimate breaking strain of 35 tons, and would thus, with a factor of safety—10—allow a safe working load of 3½ tons. The moral of all this is, construct headgear pulleys large and their axles small.

J. H. Rooney, late superintendent of the Sierra Nevada mine, has been presented by the employees of the Union shaft with a fine diamond ring.

Electric Light Dangers.—From late accounts it appears that electric lights and electric motors are not precisely the things a man wants to introduce into the bosom of his family. Kerosene is lingering, and corrosive sublimate mild compared to the innocent, slender wires which one instinctively fingers "to see how they go," and never knows what hurts him. Imagine an Irish Biddy or inquisitive porter in charge of the battery of an electric light, and wanting to turn the light up higher for company. Tenth street would be a perpetual procession of funerals en route for Calvary cemetery. Or, picture that blessed infant who is always eating matches, spilling carbolic acid, or nibbling beetle poison, attracted by the enticing array of the open battery closet, which your wife would infallibly forget to lock some day, or leave with the key in the lock. How long before Edison would be a name of horror in American families, and a frantic cry be raised for a return to pine knots and lard-oil lamps and the sweet safety of primitive methods.



THE CALIFORNIA PLANING, TONGUING AND GROOVING MACHINE.

An Inventor's Troubles.—Wm. P. Stevenson has commenced proceedings against Theo. R. Andrews and T. W. Sterling, to declare void a contract entered into on the 30th of last March, whereby Stevenson agreed to transfer to Andrews a half interest in letters patent which he was about to obtain for his improvement in hand rock drills. The cause of action is identical with the one brought a week ago to recover $86,000 damages. Stevenson also prays that a deed of conveyance be executed to him of all interest which the defendants have obtained in the letters patent; and that they deliver to him all machinery made in accordance with the invention.

A compromise has been effected between the National Millers' Association and the George T. Smith Middlings Purifier Co. by which the law suits brought by the latter against most of the prominent millers of the country, for the alleged infringement of what is known as the Cochrane patents. The suits which the Purifier Co. brought against the millers in this country aggregate in amount $36,000,000.

The product of the Leadville mills, smelters and placers for the third quarter of 1881 was $3,170,245.

The Mineral Hill Mine.

This mine is situated about 15 miles east of the town of Bishop Creek, and at the head of what is known as Black canyon. The mouth of the canyon lies about midway between Bishop and Big Pine, in the Inyo range. A road runs nearly its entire length, a distance of 12 miles. The head of the canyon opens out into a beautiful little flat, surrounded by hills, covered with pinon. At the upper end of this flat several springs of pure water bubble from the ground, which joining their forces, furnish an unfailing supply that would be amply sufficient to run a quartz mill or smelting furnace. About two miles above the springs is situated the mine, on a spur of the Inyos, running northeast by southwest. The ledge crops out along a sharp ridge, or backbone, in a formation of quartzite and lime. Considerable work has been done in the way of numerous small holes from 5 to 15 ft. in depth, scattered over the western face of the hill, and nearly all of them showing ore. From near the bottom of the hill a tunnel has been run 560 ft. in length to cut the ledge. For reasons unknown the work on this tunnel was stopped when within 200 ft. of the ledge. This tunnel would have tapped the vein about 500 ft. below the croppings. About 300 ft. above this work another tunnel has been run about 75 ft., which has cut the ledge, and about 20 tons of first-class smelting ore have been taken out. The gangue or waste of the ledge is principally calcite. Assays of several samples of the different grades of the ore show from $60 to $100 per ton in silver, and 45% of lead. The ore is composed of carbonates, oxides and sulphide of lead, and is well adapted to smelting. The mine is very conveniently situated for working. Fir timber covers the hills, and a wagon road can be easily made from the springs directly to the mine. The facilities for smelting ores at this point are unequaled. An almost inexhaustible supply of wood is close at hand, and charcoal could be delivered at a furnace for 15 cts. a bushel. The mine is owned by Uncle Peter Laird, and it has been appropriately named Mineral Hill—as the whole hill is apparently a mass of ore. At an early day this fine property will be developed and produce bullion, for we are confident that it is one of the best prospects for an unlimited quantity of smelting ores to be found in Inyo county.—*Inyo Independent.*

Not All Dead Work.

Says the Virginia *Enterprise:* The dead work now in progress at several points must presently come to an end. Indeed, much work that is now going forward cannot properly be called dead work. The crosscuts on the 2500 level of the Sierra Nevada mine are really going forward into and exploring new ground, and even the two drifts on the 2700 level of the Sierra Nevada and Union Consolidated—that going east from the Union shaft and that being run west from the joint winze to meet it—can hardly be spoken of as being dead work, as they are liable to cut the ore found above on the 2500 level; though, of course, said ore body may strike down on one side or the other of those drifts.

In the Ophir and Mexican they are actively engaged in exploring the vein on the 2900 level, and are liable at any time to find ore. This is the deepest work that is being done at the north end of the Comstock, and it is in what is for several reasons very interesting ground. Much was said about it a year or two ago, but now that the work of exploration then looked forward to is in actual progress only a few persons are giving it much attention.

In one way and another a good deal of new ground is being broken in the old bonanza mines—the California and Consolidated Virginia. All there is not, strictly speaking, dead work. No man can see an inch ahead of the picks, and ore is liable to be broken into wherever the picks are kept going. Where the Hardy vein was first cut in the Ophir—a vein which yielded nearly $2,000,000—all was solid and most unpromising porphyry to within two inches of the ore. It was, indeed, a body of rich, black sulphuret ore lying in the midst of a solid mass of porphyry. The clay seams separating the ore from the porphyry were hardly two inches in width on either side.

At the Yellow Jacket, crosscuts are now in progress on the 3000 level, and although these are still in ground that is hard and dry, they are liable at any time to cut into something more promising, even though it may not at first be ore that is encountered.

The Savage folks are drifting into ground that has never been explored, and are, therefore, likely to make discoveries of value, and at the Potosi the work of exploration on the 2400 level has only been suspended temporarily, and will be resumed as soon as better ventilation has been secured. Active operations will also be resumed by the Imperial and Alpha people in a day or two. Thus, although there is a considerable amount of dead work in progress, it cannot all be so designated, and while active exploring work is being done something is liable to turn up.

KLAMATH RIVER claims have escaped damage by the recent storm, except Austin & Co's, near the mouth of Scott river, which was filled by a break in the west dam of the China company below. They realized in the closing week 505 ounces, and took out $1,100 in the last three hours.

Nevada's Bullion Product.

The following table shows the gross yield of the mines in the State of Nevada, by counties, in gold and silver, for the six months ending Dec. 31, 1880:

	Tons.	Gross Yield.
Elko	5,224	$ 291,180.83
Esmeralda	19,178	818,957.50
Eureka	41,040	1,600,783.17
Humboldt	10,753	110,333.15
Lander	2,884	349,187.53
Lincoln	5,888	98,123.33
Lyon	29,612	175,286.97
Nye	12,151	273,881.37
Ormsby	43,404	234,913.11
Storey	92,863	1,478,774.34
White Pine	26,578	257,397.08
Totals	289,578	$5,689,323.25

The fraction of tons amounting to 3½, were omitted from the above column, but appear in total.

Net Bullion Product—	
Quarter ending Sept. 30, 1880	$ 865,470.24
Quarter ending Dec. 31, 1880	760,005.85
Total	$1,625,476.09

The following table shows the gross yield in gold and silver for the six months ending June 30, 1881:

	Tons.	Gross Yield.
Elko	2,488	$ 122,193 21
Esmeralda	19,436	749 521.83
Eureka	38,824	1,612,774.51
Humboldt	5,017	45,611 16
Lander	3,976	491,235.97
Lincoln	6 625	80,559.61
Lyon	39,760	146,778.61
Nye	6,551	188,908.45
Ormsby	7,075	35,321.21
Storey	48,857	861,831.10
Washoe	9,640	18,588 87
White Pine	5,056	189,283.28
Totals	186,339	$4,542 507 07

The fractional tons omitted in the above column amount to a little less than 5, and are added in the total.

Net Bullion Product—	
Quarter ending March 31, 1881	$ 670,748.99
Quarter ending June 30, 1881	628,873.11
Total	$1 299,622.10

Recapitulation.

Gross yield of gold and silver bullion for the 12 months ending June 30, 1881.

	Tons.	Gross Yield.
Elko	7,713	$ 413 374 04
Esmeralda	38,614	1,568,479.33
Eureka	79,895	3,213,557.68
Humboldt	15 770	155,949 31
Lander	6,860	840,423.50
Lincoln	12,514	178 682 99
Lyon	69 372	322 065.40
Nye	18,702	462,789.82
Ormsby	50,479	270,234.18
Storey	141,750	2,340.505 44
Washoe	2,640	18 588 87
White Pine	31,634	447 180.36
Totals	475,918	$10,231,830.92

Fractional tons were omitted from the above column, but added to the total.

Total net product (taxable) after deducting cost of extraction and reduction for the year ending June 30, 1881, $2 925,098.19.

HYDRAULIC GOLD.—The hydraulic mines tributary to this city—that is, which ship their gold this way—says the Nevada *Transcript* of November 10th, have produced less than $500,000 worth of bullion during the past five months, as a result of the litigation into which they have been forced by corrupt lawyers and ignorant grangers. In August, when all of the mines of note were idle, only about $50,000 was taken out in this part of the county. The period following that month was the most distressing one ever experienced in Nevada county. Not only were the laboring miners reduced to desperate straits, but thousands of mechanics, business men and other citizens shared in the terrible and never-to-be-forgotten condition of affairs. Those who were not of us then can never realize the unhappiness of that time. Hundreds of good men with families roamed here and there aimlessly, begging without avail for just enough work to keep body and soul together in their poverty-stricken homes. Had it not been for less unfortunate neighbors who had well-stocked larders and were willing to divide their last crust, the outcome would have been most disastrous.

A DISPATCH from El Paso, Texas, says that an enormous body of very rich gold, silver and copper carbonates, 40 ft. thick, has been struck in the Memphis mine, Orange mountains, east of Las Cruces. All the Germans engaged in the Batopilas Consolidated, Mexico, have stampeded; 15 were drowned while on the way to Chihuahua city. All the miners in the Cusihuiriachic and Santa Enlalia mines, near Chihuahua city, have struck because of ill-treatment and the alleged failure of the New York contractors who engaged their services. Heavy strikes of gold and silver ore are reported from Dolores district, west of Chihuahua. Stage passengers from Chihuahua report that Indians are causing great trouble to miners north and west of the city.

AT Battle Mountain, miners' wages are $3.50 per day, 10 hours, though some pay $4 in wet shafts. Carpenters' wages are from $5 to $6 per day, and stone masons $7 per day. Lumber is selling for $40 per thousand, and wood retails at from $7 to $8 per cord. Board is from $6 to $8 per week.

ISAAC THOMAS, formerly engaged in mining at Ophir, Placer county, and afterward superintendent of the Placerville Gold Quartz Co.'s mine, died at Placerville last week.

Assessments in November.

Thirty-two mines in California, Nevada and Arizona have assessments pending to become delinquent this month. These assessments show an aggregate of upwards of $1,000,000. With the exception of April and August, the above is the largest amount delinquent in any month this year. It is considerably more than will be got out of the mines in the same districts in the form of dividends this month. The assessment roll for November, which we take from the *Bulletin*, is as follows:

	Per Share.	Amount.	Del. Nov.
Belcher	$ 1 00	$104,000	1
Benton Con	25	27,000	18
Bodie Tunnel	50	50,000	24
California Gold	10	10,000	9
Caledonia	25	25,000	2
Eintracht Gravel	5	5,000	2
Excelsior W. & M	50	50,000	9
Golden Fleece	40 00	40,000	30
Goodshaw	15	15,000	17
Godfrey	2½	2,500	1
Grand Prize	25	25,000	16
Hale & Norcross	50	50,000	9
Iron Cap	2	2,000	17
Lord of Lorn	10	10,000	17
Mayflower Gravel	10	5,000	16
Mexican	1 00	100,800	8
Mono	1 00	50,000	9
Morning Star	25	20,000	22
Mt. Potosi Con	25	25,000	21
Noonday	25	25,000	29
Old Channel Gravel	1½	1,500	12
Ophir	1 00	100,800	3
Overman	50	57,600	17
Quartz Mountain	75	7,500	14
Rocky Point	5	5,000	14
Sierra Nevada	1 00	100,000	10
Star	10	10,000	28
Tuscarora Mill	25	15,000	22
Union Con	1 00	100,000	14
Utah	2 00	40,000	16
Wedge Consolidated	2½	2,500	14
Yellow Jacket	1 00	120,000	9

The money will be apportioned as follows, as to locality:

Nevada—		
Storey county	$ 841,200	
Elko	40,000	
Esmeralda	25,000	
White Pine	10,000—	$916,200
California—		
Mono county	150,900	
Placer	50,000	
Yuba	50,000	
Tuolumne	7,500	
Sierra	5,000	
Nevada	2,500	
Butte	1,500—	266,500
Arizona—		
Cochise county	2,500	
Yuma	2,000—	4,500
Total	$1,187,200	$1,187,200

Some of the mines in the above list have had a varied career, while the history of others shows one continuous demand on stockholders without a single compensating feature. Belcher has been twice on the dividend list, and has paid altogether $15,397,200, but it has not paid a dividend since April, 1876. Most of the $2,432,000 in assessments for this mine has been levied in the last five years. There are those who still believe that Belcher will again come to the front as a prosperous mine. The Benton Consolidated mine has called upon stockholders six times since its reorganization a few years ago. The demands have been small, the total being only $270,000, but there have been no dividends. Flattering prospects have been accorded to Bodie tunnel by interested parties, but dividends are still delayed. In the meantime, five assessments of $80,070 have been levied. The California mine mentioned above is in Mono county, and it is still an assessment proposition. The Caledonia mine of Storey county has severely tested the patience and faith of its owners, having called for $2,085,000, but not a dollar has it given back. The Eintracht gravel mine is in Sierra county, and hopes are expressed that it will eventually more than pay back all it has required for its development. The Excelsior water and mining company's property is in Yuba county. The mine was paying nicely until the agitation of the debris question, and the present assessment is understood to meet an expense for impounding its tailings, so that work may be renewed without prejudice to any one.

The Godfrey is a gravel claim in Nevada county that is expected to be remunerative some time. The most we know about the Golden Fleece mine of Placer county is that its assessments are always for large amounts per share, and the above is the 23d assessment. The Goodshaw is in Mono county, and it has called for $160,000. The Grand Prize has had its ups and downs. It has paid $450,000 in dividends, the last one being paid in September, 1880, and it has levied $340,000 in assessments. It is now in an embarrassed condition. Hale & Norcross has been long before the public, and it has had its days of prosperity and adversity. It has probably levied more assessments than any other mine on the Comstock lode. The present is unmbered 71, showing a total of $3,754,000, against $1,598,000 in dividends, the last of which was paid in April, 1871. Thus for over 10 years this mine has been a burden to the owners. The Iron Cap is in Yuma county, Arizona, and four small demands have been made. Only two assessments have been levied by the Lord of Lorn of Storey county. The Mayflower is a gravel claim in Placer county. The Mexican is the northern half of the Ophir mine, and the assessments levied by it aggregate $1,783,000. The Mono is the southern half of the Bodie. Its assessment account foots up $450,000. Both Mexican and Mono were launched on the reputation of their better halves. The above is the first assessment on the Morning Star, which is a Storey county claim. The Mt. Potosi Con. has had great trouble in collecting late assessments, on account of litigation respecting the management. It is presumed that the present tax will be paid, as the difficulties appear to have been settled. The Noonday has called for $93,000, in addition to the value of the bullion produced from ore raised. The Old Channel is a gravel claim in Butte county. The Ophir claim is one of the first discovered on the Comstock lode. The mine has had several periods of prosperity, but is now in horasco. The assessments aggregate $3,143,400, to which should be added those collected by the Mexican, making a total of $4,976,400, against $1,595,800 in dividends, the last of which was paid in January, 1880. The Overman mine has been before the public for nearly a score of years. In the meantime, it has called for $3,518,300, but there is very little to show for the outlay. The Quartz Mountain is in Tuolumne county, and there have been 13 assessments. The Rocky Point is a Placer county claim. Sierra Nevada has levied 70 assessments, the total aggregating $4,650,000, and most of this sum has been collected within the last five years. Prior to 1871, it paid $102,500 in dividends. The Star mine has been producing from $20,000 to $30,000 in silver per month for some time and yet it has asked for $180,000. The Tuscarora has called for $110,000. Union Con. and Utah have paid no dividends, but the former has collected $1,260,000, and the latter $1,230,000 in assessments. The Wedge Con. is in Cochise county, Tombstone district, Arizona. Its first assessment of five cents per share, levied in September last, was rescinded in October, when the present one was substituted. It is a little over 10 years since Yellow Jacket paid its last dividend, and the total is $2,184,000. Assessments, however, have been kept up with great regularity ever since. The original capital was all paid up in this way. Then the capital was increased to $12,000,000, and the total paid on account is $5,238,000. The Comstock lode has not yielded a dividend since August, 1880, and it is difficult to give an idea when the next one will be paid. The delinquent assessment roll for the first 11 months of the year compares as follows:

	Mines.	Amount.
January	30	$ 780,500
February	29	880,400
March	29	417,400
April	39	1,068,450
May	28	678,800
June	29	754,810
July	30	570,900
August	33	1,218,300
September	32	809,000
October	31	633,250
November	32	1,187,200
Totals	342	$9,005,010
In 1880	439	12,038,800
In 1879	463	13,921,100

THE BIG BEND TUNNEL.—Innumerable questions are asked by gentlemen as to whether the proposed tunnel on the Big Bend will have the capacity to carry the water. In conversation with engineer McGann, who has done a greater part of the surveying, and who has made the calculations and drawn the plans, we learn the following facts in relation to the project: The size of the flume that was put in the river of the old Cape claim, years ago, was 40 ft. wide and 4 ft. deep, making a sectional area of 160 cubic ft., with a grade of six inches to 100 ft. This was of sufficient size to carry the water of the main Feather at its low stage. The Big Bend tunnel will be 18 ft. wide, 12 ft. high, with a vereed sine of 3 ft. The area of the wet section will be 216 cubic ft., and it will have a grade of 53 ft. to the mile. That zone in the upper portion of the tunnel is calculated for air passage. This tunnel will carry nearly double as much water as there is in the main Feather river at its ordinary hight, and has the following facts in its favor: That it is only required to take what water there is in the North fork, while the Cape flume had to contend with the waters of the West branch, South fork, Middle fork and North fork. Consequently, it is safe to assume that a tunnel of the above capacity will take all the waters of the north for at least seven months in each year. Mr. McGann has just returned from a trip up the Big Bend, and states that Mike Wells, who has the contract to build the road to the mouth of the tunnel, has 15 men at work already, and part of the road is completed. The boarding-houses have been erected, and everything is being pushed ahead with great rapidity.—*Oroville Mercury.*

HOW THEY DO IT DOWN IN MAINE.—The following, from the Maine *Mining Journal*, shows how they run the mining stock business in that land of booms: "We suppose there must be a parcel of bandsome and talented brokers getting together on the floor of the mining board and tossing a certain stock about from one to another until 'sales' have amounted to many thousand shares, while not a half a dozen shares have changed hands, and then publishing in the evening and morning papers a quarter of a yard of reported 'transactions;' but to the unappreciative outsider, it would seem that full-grown men should be in better business."

A RICH MINE.—The Natchez mine, near Dun Glen, in Humboldt county, which was abandoned some years ago, was relocated lately, and shows up very rich. At 25 ft. below the surface a ledge was uncovered three and a half ft. wide, six inches of which is in ore that assays from $500 to $1,000 to the ton, and the rest of which goes $75. It is a contact vein, having a limestone hanging wall and porphyritic foot wall.

MECHANICAL PROGRESS.

Joining Substances by Pressure.

About two years ago several experiments were made by Walthere Spring in regard to joining substances by pressure, the pressure used being, in many instances, as high as 20,000 atmospheres. Nitrate of potash and nitrate of soda were compressed from the state of powder into small hard blocks, which were more solid than if made by fusion, and the original separate particles composing them could not be traced.

The possibility being thus proved of uniting solids by pressure, it remained to extend the experiments over a large number of substances, to make trials in a vacuum, and to ascertain the effect of temperature on the readiness with which the union could be produced. In the preliminary experiments of Mr. Spring, the compression was effected by a ram working in a steel cylinder by means of a screw and hand lever. The solid blocks produced were, however, very difficult to get out whole, and the pressure exerted upon them could only be roughly estimated. In the late experiments, therefore, the pressure was produced by loading a lever with dead weights, and the cylinder or die in which the substances were compressed was composed of two separable parts, held together tightly at the top by a nut, the lower part fitting into a recessed base plate; they could thus be taken apart for getting the compressed block out without injuring it. The die was covered by a gun metal bell or air-tight receiver, from which the air could be exhausted for experimenting in a vacuum. The ram, loaded by the lever, passed into the cylinder through a stuffing box in the top of the bell. It was found, however, that the pressure could not be increased beyond 10,000 atmospheres, the steel ram itself crushing at this limit, being replaced by another after each operation. The presence or absence of air had scarcely any perceptible effect in the experiments, and on this account, together with the fact of the crushing of the ram, the old apparatus with the screw was ultimately adopted again.

In regard to trying the substances in a heated state, it should be observed that those giving good results without it, were not tested in that way. Eight metals were tried by Mr. Spring, and all except zinc were compressed at a temperature of 57° F. From lead filings, compressed in a vacuum under about 2,000 atmospheres, a block was obtained as solid as if cast by melting, and the microscope failed to detect the slightest trace of the original constituent particles. At 5,000 atmospheres the lead would no longer stand under the ram, but oozed out through all the joints like a liquid, allowing the ram to be driven down to the very bottom of the die. On opening the die, the fine flakes of lead leaf had exactly the appearance of sheet lead produced by rolling, conformably with the result of M. Tresca's experiments on the flow of solids. The specific gravity of the compressed lead was found to be 11.5 instead of 11.3. Bismuth, though so brittle and easily pulverized, yet joins again readily under pressure; a block compressed from fine powder under 6,000 atmospheres breaks with a crystalline fracture, just as though it had been cast; and the same holds true for almost all the other substances tried. Tin filings join perfectly under 3,000 atmospheres; at 5,000, the tin begins to flow out through the joints of the die, but soon stops; at 5,500 begins again, and again stops; and so on up to 7,500 atmospheres, under which pressure the flow becomes continuous.

Zinc filings join perfectly under 5,000 atmospheres, and under 7,000, the compressed block barely begins to flow. Joining less readily than the other metals already cited, zinc forms a good illustration of what takes place also in the compression of all the other substances tried, proving that union depends solely on the closeness with which the particles are brought into contact. Under no more than 260 atmospheres pressure, zinc filings do not join. Under 700 they so far join as to come out of the die in a block, which, however, breaks very easily and then falls to dust; a microscope shows distinct spaces between the filings in the block. Compressed under 2,000 atmospheres, the block will hold together under the file, but breaks under the hammer; its fracture still shows spaces between some of the filings, though much fewer, while others of the particles are now clearly seen to have become perfectly joined. With 4,000 atmospheres, very few interstices can be detected; and with 5,000, the block is perfectly solid throughout, and stands gripping in a vice and filing and hammering like a block cast by melting. A trial was also made of compressing pulverized zinc at the temperature at which it is most malleable, namely, about 266° F. It then joins still better, and the block breaks with a crystalline fracture.

Aluminium joins too weakly under 4,000 atmospheres to stand filing; under 5,000 it stands filing, but not hammering, while with 6,000, it joins perfectly and becomes malleable. The same holds good with regard to copper. In the case of antimony, the trial was not made with filings, but with the finest powder possible, in order to ascertain what pressure would reproduce the metallic luster which is lost in the state of powder. With 5,000 atmospheres, the luster reappeared on the surface of compressed block, but its center remained pulverulent and dull gray; under higher pressures the luster penetrated deeper and deeper in from the surface. Spongy platinum begins to join under 5,000 atmospheres, with metallic luster on the surface; but the block is friable and the fracture dull, and higher pressures do not produce so perfect a union as in the preceding instances. The readiness with which these metals join is seen to be inversely as their hardness, and as the hardness generally diminishes with rise of temperature, it may be concluded that the softer a metal becomes by heating, the more readily will it weld, just as iron gets very soft before melting, and welds easily.

Other experiments were made with metalloids, oxides, sulphides, salts and carbon compounds, which, however, will not be considered here, those given above being of greater practical interest.

INCREASING THE RESISTANCE OF IRON TO TENSION AND TORSION.—M. Seguin, of Paris, has patented a process for increasing the resistance of iron to tension, torsion and transverse strains, by immersing them wholly or partly in hot diluted sulphuric or hydrochloric acid, or in a mixture of one part of turpentine in five or six parts of water. In the acid method the metal is raised to a cherry-red heat, and then dipped in a solution of equal parts, by volume, of sulphuric acid of 60 degrees strength and of water. In the turpentine method the mixture must be kept constantly stirred, lest the spirit should float upon the surface and take fire, on the introduction of the glowing metal. In either process the metal is held in the solution till it has sunk to the temperature of the latter, and is then quickly thrown into cold water. The various implements, such as hooks, levers, beams, etc., subjected to this process, need only be partially immersed in the solution, the portions selected for treatment in each case being, of course, those which will necessarily be subjected to the greater strains when in actual use.

AN EXPANDING MANDREL.—An expanding mandrel recently introduced consists of two parts, viz.: a ribbed split sleeve and the mandrel proper. The sleeve, which is made of steel, is pierced with a tapering hole, and one end of the mandrel is turned to exactly fit this hole. The sleeve is then turned to the required diameter, preferably on the mandrel to which it belongs, after which the material is removed in such a way as to leave three narrow longitudinal bearings with equal depressed spaces between them. These depressions extend very nearly to the bore of the sleeve, leaving only sufficient metal to hold the bearings in position. The sleeve is cut apart through one of these depressions, leaving it free to contract or expand. In using the mandrel, the sleeve is placed in the hole, where, by lightly driving the mandrel into it, expansion will occur, and the three bearing surfaces will be forced into sufficient contact. The contrivance is simple in construction, can be readily and inexpensively made as required for use in a machine shop, and can also be advantageously manufactured and sold as a standard tool.

PULLMAN CARS IN EUROPE.—There are now 47 Pullman cars in use on English and Continental railways, and 10 more in course of construction to be sent abroad. The first Pullman sleeper introduced in England commenced running on the Midland railway in 1874. The English railway officials and the people generally, predicted that the cars were too long to get around the sharp curves of that road, but after a trial had satisfied them that there was no ground for apprehension on this score, the English companies commenced to build larger carriages than they had ever built before.

HOW TO MAKE BRASS SPRINGS.—Brass cannot be tempered in the manner in which steel is tempered. Hence, the only method to make a brass spring is to compress the metal either by rolls or by hammering. If the springs are to be flat, hammer them out to shape in thickness from soft wire, or sheet brass, some thicker than the finished spring is to be. If the brass shows a tendency to crack in hammering, it must be annealed, which can be done by heating to a light red and plunging into water. In hammering use a light hammer, and don't spare the blows.

BUFFALO SKINS FOR GEAR WHEELS.—There seems to be no end to substitutes for iron in the manufacture of gear wheels. The last suggestion is raw buffalo hide. Cement and press together as many layers as are required for the breadth of the wheel. The blanks thus prepared are cut to form the teeth in the usual manner with suitable tools. The advantages claimed are, smooth and noiseless action at very high speeds and greater durability without lubrication.

A NEW MOTOR — ANOTHER KEELY.—The *Schlesische Presse* describes a new motor, which is said to be driven by a new force more powerful than steam, which has the additional advantage that it can be generated in about five minutes, without the aid of fire or water, to attain a pressure of ten atmospheres without emitting any noxious vapors. The particular machine rates two horse-power, while occupying a space of but 11½ cubic ft., and weighs, with the motive power, but 330 lbs. We should be glad to see it.

SCIENTIFIC PROGRESS.

Cosmic Physiology.

At the late meeting of the American Association for the Advancement of Science, Prof. T. Sterry Hunt read a paper entitled "Historic Notes on Cosmic Physiology." The term physiology was used in its general sense as applied to the physiology of the universe. One of the great questions in this direction is an inquiry into the nature of interstellar space, and what is the substance which pervades that vast space. This question was first discussed by the great Arabian scholar Alhosen, and it is a fact worth knowing that he was the first to conclude that the terrestrial atmosphere was of quite limited extent; but he conceived the necessity of some ethereal substance beyond.

There can be no doubt but that beyond our atmosphere, and throughout interstellar space, gaseous particles float, and form some connection between the heavenly bodies. Sir William Grote discussed the probability of a "luminiferous ether," which he identified as Sir Isaac Newton's "chemical particles." The same view was adopted by Sir William Thompson, and more recently by Mr. Williams, who, in his book on "The Fuel of the Sun," advanced the idea that it was these particles of gaseous matter which hoarded the solar heat lost by radiation.

Prof. Hunt then discussed the relations of this spiritous fluid to our planet and other planets. He said that processes have been going on in the chemical changes of the earth from the earliest ages which have absorbed and evolved enormous quantities of gases. For instance, in the manufacture of the limestone rocks of the earth alone, over two hundred times the amount of the carbonite dioxide now in our atmosphere have been consumed. This must have been borrowed from space. He went on to discuss the probability of a chemically-compound ether existing in that interstellar space and pervading the universe just as the atmosphere surrounds the earth, although in minute particles and exceedingly attenuated.

The paper was listened to with the greatest attention, and was discussed with more animation than any other thus far read. It was debated till long after the hour of adjournment, and then postponed till the next day. Prof. Hunt's original ideas are so opposed to existing theories that it is often some time before they are adopted.

IRIDIUM INSTEAD OF CARBON FOR ELECTRIC LAMPS.—A promising improvement has been made in electric lighting by substituting electrodes of iridium for the carbon pencils hitherto almost exclusively used as poles in exhibiting the voltaic arc. Iridium is fusible only in the arc from a very powerful battery, and by keeping the intensity of the current below a given point, the metal can be maintained at a temperature of about 4,000° F., which is far below its melting point, though high enough to add the light of an intense incandescence to the brilliancy of the arc itself. At this temperature the iridium points remain completely unchanged, and the variations and flickerings due to the rapid wearing away of carbon pencils, are entirely absent in the new light; while the consistency with which the source of illumination keeps its place peculiarly adapts it for use in the focus of the Fresnel lenses, or the paraboloic reflectors which in lighthouses or in similar situations take their place. The process by which the iridium, naturally a gritty and intractable powder, is formed into pencils for use in lamps is an ingenious adaptation of a patent issued long ago for making the same metal into points for gold pens, and depends upon the property which iridium possesses of forming a compound with phosphorus, which can then be melted at a temperature of about 3,000° F.—about the fusing point of iron—and molded into masses which can be subsequently dephosphorized, and regain the original infusibility of the pure metal.

THE EARTH'S POLARITY.—Nile's *Weekly Register* for 1836 says that Prof. Lariat, well known at that time as a skilled and scientific balloonist, at one of his ascensions in New York, reached an altitude of about five miles, and proceeded over 100 miles. He passed through clouds of sleet which covered his balloon with icy particles, but what was more interesting, he discovered that when at his greatest altitude, the needle of a compass he had with him did not have the least tendency to exhibit polar attraction, but wavered about at all points of the compass. This circumstance of the earth's polarity at that distance from the surface is worthy of investigation, and merits the attention of scientific minds. We are not aware whether these observations have been corroborated or otherwise by later balloonists.

ALL chemical actions, says M. E. J. Mammene, in *Les Mondes*, may be regarded as actions either of contact or of mixture, and are regulated in the former case by specific gravity and molecular weight—in a word, by the molecular volume of the bodies present, and in the second case by their molecular weight. In the general hypothesis of chemical action which he advances, he rejects entirely the usually accepted notions of molecule and atoms, and substitutes what are conveyed by the terms equivalent and atomic volume.

The Lumber Question.

The question of our future lumber supply was discussed from a scientific point of view at the late meeting of the American Association for the Advancement of Science. The discussion was introduced by the reading of an elaborate paper by William Hosea Ballou, of Evanston, Ill., on "The White Pine: Its Origin and Natural History; Statistics of Its Industry in Michigan; The Coming Substitute for Lumber." This paper possessed much general and commercial as well as scientific value, and if space permitted, would be given in full. We give its concluding portion on the Michigan lumber trade, which will be read with peculiar interest as relating to a region which has recently been devastated by such terrible forest fires.

There are 20,000 vessels engaged in the transportation of this lumber, employing 120,000 men, and valued at $100,000,000.

In the log woods in winter are 50,000 men at work, and 20,000 in the sawmills in summer.

There are 30,000 animals thus engaged, one-third of which are oxen and the remainder horses.

There is a total of 190,000 men, 30,000 animals, and a total capital invested in mills of $111,750,000. The lumber taken annually since 1835, has sold for $1,500,000,000.

The ancient lower limit of the white pine belt extended from Grand Haven to Port Huron, dipping on the west side of the State to Kalamazoo. The whole pine area now comprises 288 townships, in 18 counties, in the lower peninsula, embracing 10,268 square miles, or 6,571,520 acres; in the upper peninsula, 179 townships, or 4,134,160 acres.

It almost seems like a task of despair to hope to raise the forests for another such enormous production. Science will doubtless devise other materials as a substitute. Indeed, I have been shown a material manufactured in Chicago in the shape of a board one inch thick, made from wheat straw, which can be colored to represent any lumber now known, so accurately as to deceive the eye. The inventor manufactures 2,000 square ft. from a ton of straw. It is more durable and much cheaper than lumber. As a parallel to the use of paper wheels, Mr. Pullman is now finishing off palace cars in this material. The limit of its manufacture will depend only on the production of wheat straw.

FAURE'S ACCUMULATORS.—Among the many other practical uses to which Faure's electrical accumulator may be put, it has been suggested that it might be employed to utilize the waste of water power during the hours at which such heavy power may not be employed in ordinary work, as at night, etc. In many localities the circumstances are such that it might be profitably employed in storing up such energy. There is also a very valuable use of the accumulator in its application as an adjunct to the dynamo, regulating the light-giving current and storing up an irregular surplus in such a manner that stoppage of the engine would not stop the light but only reduce it slightly, and that there would always be a good residue of two or three hours of full lighting power, or a supply of 8 or 10 hours of light for a diminished number of lamps. Sir William Thompson has constructed an instrument to make and break the circuit between Faure's battery and the dynamo, and thus fulfil automatically the conditions for the economical use of generating machines and the regulation of the supply of electricity for the lamps. The instrument also guards the coils of the dynamo from damage and prevents loss in the accumulator.

IS THE TELEPHONE A RECENT DISCOVERY?—The present discussion in our courts and elsewhere, in regard to the validity of the patent claim, assuming that Prof. Bell was the original discoverer of the fact that conversation may be carried on at a distance through the medium of an ordinary telegraph wire, may possibly be somewhat elucidated by the following extract from a published work on electrical subjects, printed in 1858, in which the writer speaks thus of the "telegraphone:" "The idea of using the earth circuit; the possibility of employing a single wire; any method of recording the magnetic current—in other words, of not only *making it speak*, but of reporting and preserving *its utterances*—all these were unknown elements, which it was left for the present generation to discover." The writer of the above certainly knew what he was talking about, and had discovered that electricity could be made to "speak" and "utter" vocal sounds. And this was in the year 1858!

CHROME STEEL ARMOR PLATES.—Experiments have been made at Gavres with armor plates made with chrome steel. The plates were of the compound variety; that is to say, they had a chrome steel front and solid backing of iron. The steel in such plates is intended to resist penetration, and the iron to prevent fracture. But the results at Gavres were not at all successful. The first projectile which hit the plate shattered it. It is thought that the union of the iron with the steel was not sufficiently intimate, and that the iron itself was not solid enough.

PRECIOUS METALS IN THE ARTS.—During the last fiscal year over $12,000,000 worth of gold and silver were used in the arts and manufactures in the United States. If gold were to be demonetized by the whole world it would still command nearly its present value for use in the arts.

The Mining Share Market.

The mining share market continues very weak indeed. A long drag of dullness and low pricee in the Comstock market, such ae hae been undergone for several weeks, almost invariably culminates in a sharp decline, which is alarming to the average holder. People become uneasy and frightened at the staleness of speculation, and imagine things which really do not exist. Finally, a numher of them throw their stocks on the market, and bring about the very disaster in which they stood in dread.

A survey of the drift leading from the Chollar-Norcross-Savage shaft has heen made which shows that it hae further to go to connect with the main incline than was at first supposed. It was thought that the distance was 160 ft., but the survey ehows the distance was 193 ft. They have run 78 ft. of this distance, leaving 115 yet to go. The rock is of a deep hlack color and so hard that it will ecratch glass as readily as a piece of jasper or agate, yet they are making excellent progrese in it. This rock ie undonbtedly the same hard helt that was cut east of the vein nearer the surface in running the old Gould & Curry lower tunnel. It presents the same appearance and characteristics in every respect.

The hlowers now deliver a eupply of air at the face of the drift sufficient to allow of the men working quite comfortably. The taking out of the hulkhead between the Chollar-Norcross-Savage ehaft and the Hale and Norcross has also materially contrihuted toward the cooling off of the 2400 level.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Pay-Day G. & M. Co., Nov. 12th. Locatiou: Arizoua and New Mexico. Capital atock, $10,000,000. Directors—R. H. Lloyd, John Shirley, John A. Drinkhouse, Joseph Brandenatein and Tbomas J. Cluuie.

Monumental Tunnel & M. Co., Nov. 12th. Location: Eureka county, Nevada. Capital stock, $10,000,000. Directors—L. L. Robiuson, W. S. Wood, W. M. Stewart, E. N. Robinsou and Henry Pichoir.

San Francisco Carmaker's Protective Society, Nov. 14th. There is no capital st ock, and the Directors are William Beck, Albert Johnson, Milton Brodie, James Neil, Jr., and Luther Hendry.

Mexico Cold Placer M. Co., Nov. 16th. Location: State of Sinaloa, Mexico. Capital stock, $100,000. Directors—A. D. Allen, Edward Norton, C. L. Pidwell, James H. Cates and David Buck, all of San Francisco.

Little Chief M. Co., Nov. 16th. Location: Magnolia district, Butte county, Cal. Capital stock, $80,000, in 800 shares. Directors—T. Schumacher, A. L. Collina, S. C. Deau, George S. Clark, E. B. Deau of San Francisco.

IT is now pretty well known what portion of the area of the mining ground of the western slope of the Sierra Nevada mountains will he displaced and sent down stream in carrying on hydraulic miuing. The dirt to he used that way can he measured or even approximately weighed in pounds of avoirdupois.

Artesian Well Tubes.

The principal difficulty in the ordiuary mode of sinking and tuhing arteeian wells is to forcs the pipe in tuhing in uniform size down to any conoiderable depth, owing to the lateral pressure of the surrounding earth, and the usual result is, at a depth of from 100 to 200 ft., the lateral pressure ie so great that the pipe cannot he moved down with all the force availahle. Tho only alteruative is to put down a smaller pipe inside of the first, and repeat the same as often as the pipe gete stuck fast, and hy that mode, if the well should reach a dopth of 507 or 600 ft., it would he of little practical value, as the diameter of the pipe at the hottom would he so small.

B. R. Norton, of Alameda, has obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for an improvement which ie deeigned to overcome this obstacle. By his improved method he makes the well tuhing conical and inclined ahout two or three inches to the 100 ft., with the large end at the hottom, hy which means he not only avoids the difficulty of getting the pipe etuck fast and held hy the lateral pressure of the surrouuding earth, hut utilizes the latsral pressure in forcing the pipe down—very little force more than the weight of the pipe and the lateral pressure—where the earth ie excavated inside and underneath the pipe.

A well say of 1,000 ft. would he started with pipe 30 iuches in diameter, and inclined two inches to the 100 ft., it would terminate at the top with pipe 10 inches diameter, which practically would he eqnal iu value to a well 30 inches in diameter the entire depth, and would cost less; and further, it would he impossihle to sink a well 100 ft. of 30 inches diameter of uniform siss pipe. A well constructed with conical pipe as proposed, would he like receiving the water into the large end of the funnel instead of the small end, as hy the old mode.

The boring or excavating of the well for the conical pipe can he done hy hand or steam power, and with any of the well-known tools. The inventor prefers sand pumps constructed of half-inch boiler plate, armed on the hottom with heavy barhed irons for picking or loosening tho earth or rock, the whole weighing 500 or 600 lbs., and worked by a rope attached to a hoisting engine, alternately hoisting and letting it drop eight or ten ft., which would loosen the earth and fill the sand pump with the loosened material. The eand pump would he constantly changed in position, so that it would not etrike in the same place, and spring tools would he used to cut away the earth from under the edge of the pipe.

Each inner section extends about half way into the outside section helow, and is secured to it. The upper end projects out, so that the next section above slopes over it. The inner pipes all abnt, so that the tuhe ie douhle throughout its whole length, and has the strength of hoth tuhes.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

WORK.—Monitor *Argus*, Nov. 14: Work is progressing on the Polaris and North Colorado mines in the Monitor mining district. Our mines are looking up, and no doubt there will be some facts as to the buried wealth of this region laid bare creanother year shall roll by, that will open the eyes of the mining world to the great opportunities they have perhaps lost. The owners of the Alpine placer claim, which is situated just below Hangman bridge, are hauling lumber aod preparing to commence operations at that place in a short time.

AMADOR.

MORGAN'S TUNNEL.—Amador *Ledger*, Nov. 12: A considerable body of ore has been encountered in the tunneling operations at Murphy's ridge. In one spot the ledge was 3 ft thick, and is said to range from this thickness down to 8 inches. The ore is full of sulphurets, but no free gold is visible to the naked eye. There is no question, however, that it is fair paying rock.

MISCELLANEOUS.—Mining at the Amador Gravel claim has not yet been recommenced, although everything seems to be in readiness for work.

DOWNS.—Amador *Sentinel*, Nov. 9: Work has been resumed at the Downs mine. Their full force of men is not at work yet on account of the scarcity of water to drive the mill. Sinking in the Golden Gate shaft is near completion; the ledge still holds its richness and size. Very little news from the Pioneer district. The Acme mining company, under the superintendency of Mr. D. B. Kelly is working on its new quartz mill.

CALAVERAS.

COMMENCED WORK.—*Chronicle*, Nov. 12: The water supply has so far increased sufficiently to enable some of the hydraulic claims in this vicinity to commence work. Preparations for the winter's run are being made in all, and in some everything is in readiness to go ahead. Operations have commenced in the Mammoth hydraulic claim on Tunnel Ridge, and it will not be long now before all the claims on the Ridge will be in active operation.

ARASTRA.—*Mountain Echo*, Nov. 9: Robert Leeper has completely renovated his arastra mill and is now ready for crushing. Considerable improvement is going on in Angels, and things begin to look encouraging. Bennett & Co. are still at work on the Raspberry mine. The ore is looking well. Several clean-ups have recently been made from the mine, none of which has paid less than $15 per ton, and at a depth of 20 ft the vein is over 5 ft in width.

EL DORADO.

NEW GRAVEL MILL.—*Mountain Democrat*, Nov. 12: Nelson Dunn has completed his contract on the 10-stamp gravel mill for the Highville mine, Newtown, and it will be started up for trial to-day, and probably for permanent operations next Monday or Tuesday.

A FINE MINE IDLE.—A short distance southwest of the celebrated Springfield mine, near the Cosumnes river and the Amador county line, is the Montezuma mine, owned O. P. Harland M. G. Griffith. On the surface, in the "early days," a number of Spaniards gouged into the seams here the quartz thus extracted on their heads down to an arrastra near the creek, and realized big wages in crushing and washing it. In this way they and their successors, out of a cut 12 to 15 ft wide and not more than 100 ft long, took out several thousand dollars. The traditions relating to their success led other parties many years later to explore the underlying ledge, and the location of the Montezuma, which is a strong ledge, varying from 3½ to 8 ft in width, with well-defined walls and a fine gouge. A shaft was sunk, a tunnel run, and there was a "spurt" of high-pressure mining. The quartz, however, so far as they worked it, yielded from $15 to $80 per ton. Mr. Hart, an old resident of the vicinity, entered into copartnership with Mr. Griffith, and they put up a 10-stamp mill, run by water power, but when they had run it a short time, and had realized about enough to put hoisting works and other needed machinery, the dam at the head of their ditch was washed away, and in putting in a new one that might be relied on to resist future floods they exhausted the means realized from their previous workings, and now the mill stands idle, with a splendid water-power running to waste, until they can get their affairs into such shape as to put up the machinery that is necessary to the proper working of the mine.

RICH SPECIMENS.—Placer *Argus*, Nov. 12: A party of four men who have been prospecting on the El Dorado side of the river, came into town last Saturday with some $2,000 worth of specimens, which they found near the top of the hill. They had, during the preceding two or three weeks, obtained several hundred dollars in the same vicinity. They say they have struck a quartz ledge 6 inches wide.

INYO.

PANAMINT.—Inyo *Independent*, Nov. 12: Superintendent Purdy, of the Inyo consolidated mining company, is now engaged in extracting ore from the Little Chief, Wyoming, Eureka and Independence mines. The company have a number of other good paying mines, but have not the men at present to work them all. As soon as the company's stores arrive from San Francisco, 150 men, including chloriders, and others will be employed. There is now at the mill about 500 tons of fine ore, which will be worked as soon as some little repairs are completed on the mill. Pack trains are busy getting in wood, and ore is being delivered at the mill by tramway. As soon as repairs are completed, a long and profitable run will no doubt be made, which will enable the company to materially increase their dividends.

LOOKOUT.—Preparations are being made to start up the Modoc furnaces during the coming week, under the general management of Frank Fitzgerald. J. J. Williams, formerly superintendent of the New Coso, will take charge of the furnaces during the run. About 200 tons of ore from the Minnietta and Modock mines are now on the ground. Al. Robinson's mule train is packing 15 tons of rich ore from Panamint, in addition 100 tons of fine dust will be put through. The run will produce about 100 tons of bullion, which will be shipped during the present month.

NEW WORK.—A letter from Cerro Gordo says that several men have been put to work on the old Union mine, Capt. Keller has put some men at work on Ygnacio Hill, at Cerro Gordo.

LOOKING UP.—The prospects at the southern end of the county are decidedly brightening. Panamint, Lookout and Darwin will all be producing bullion in a few days.

KERN.

THE NEW SILVER MINING DISTRICT.—Kern County *Californian*, Nov. 12: We have been shown a quantity of specimens of the ore from the new silver district recently found, that we have before alluded to, on the north side of Erskino creek, about 2½ miles from Hot Springs. It appears to be free milling ore, and the samples indicate that the pay streaks are enormously rich. Seven leads have been found and the principal one has been traced a mile, showing equally well in every part. A gentleman familiar with silver mines, who examined them, states that the prospect is splendid, and if it had been found anywhere within 50 miles of the Comstock an old fashioned mining excitement would have been the result.

MARIPOSA.

SILVER DISTRICT.—Mariposa *Gazette*, Nov. 12: We were called upon on Tuesday last by Mr. Morse May, of Modesto, who is engaged in opening a vein lode of silver ore, running parallel about half a mile west of the mine

and works of the Modesto Silver mining company. At his point Mr. May located a vein and claim of 1500 ft, upon which he has sunk a shaft 50 ft deep, and shows a vein 2 ft thick, between well defined walls 4 ft apart. The vein at the bottom of the shaft indicates an increasing width as it goes down. But one test as yet has been made of the ore, which assayed $27 per ton. A contract has been made to sink the shaft another 50 ft, which is expected to be done by Christmas. This is certainly a promising outlook for the Silver District, which is quite contiguous to our town.

THE MODESTO SILVER MINE.—Mr. Moses May, of Modesto, who is operating in the same mining district, informs us that Mr. C. F. Leavensworth, the lessee of the mine and works is progressing rapidly with his work, in constructing machinery upon the mine. Nearly all the machinery of the 10-stamp mill is upon the ground, and the hoisting works will be completed and ready for use in 6 or 8 days. Mr. Leavensworth has a full force of assistants for present purposes.

MONO.

BODIE.—*Free Press*, Nov. 15: There are 3 points of interest on the mineral belt of this district, and as time passes the interest in them increases. We have reference to the Standard, Lent and Red Cloud shafts. The three companies that control these properties are the ones who will determine whether or not the rich veins found near the surface extend to great depth—1200, 1500 or 2000 ft beneath the surface. Quartz mining is always an uncertain business, as indications are often deceptive and men are led astray by formations altogether kindly. No one for a moment doubts but that Bodie district has more than passing merit, and if there is anything whatever in "indications," the camp has yet to see its best days. The Standard shaft is down 1100 ft, and it will oo sunk to still greater depth. The management is satisfied that the development unde below this point will overshadow the upper levels. The Lent shaft has reached the depth of 800 ft, and they will soon commence crosscutting from that level. The Red Cloud shaft is being driven down, and it is now at a point 649 ft below the surface, with a slight increase of water. The future workings of these three large shafts will bo watched with interest. Now that the railroad is completed timbers and wood for the mines will commence to come at a lively rate. The Standard will be the first to be supplied, and the balance will be served in their turn. This is an important work. There need be no delays in the mines on account of a lack of material, for the railroad trains will go and come throughout the winter. There is no change to note in the other mines, as the review will prove. The outlook for the winter here is good—better than in most of the mining districts, and capitalists are confident that in a few months matters will be much brighter than at present.

NEVADA.

CENTENNIAL MINE.—*Transcript*, Nov. 13: The shaft of the Centennial mine is being sunk from the 4th to the 5th level. The levels will be 120 ft apart, and 30 ft of the distance has been sunk, and a ledge of fine ore is presented in the shaft. With the opening of the 5th level a large amount of rich ore will be accessible in the backs above, and will go to something like the old figures of from $80 to $100 per load.

QUARTZ LEDGE.—North San Juan *Times*, Nov. 12: About a year ago a quartz ledge was discovered on Buckeye Hill, within the boundaries of the placer claim then owned by George D. McLean, which, if all accounts be true, and we do not doubt them, will prove a bonanza to the owners. A tunnel was run from Sweetland creek, which has tapped the ledge about 20 ft below the surface, at which point the ledge was nearly 2½ ft wide. Mr. Powers took to Virginia City a quantity of rock which assayed from $8 to $16 per ton. The white rock, which apparently contained neither gold or silver, assayed $8 to the ton, while the blue rock assayed $16 and over to the ton. The original locators have consolidated their claims and are preparing to run another tunnel to the ledge, which will tap it over 100 ft below the surface. They have great confidence in the ledge.

GRAVEL MINE LEASED.—James E. Broderick has leased his valuable gravel claim at Little Grass Valley, to some French Corral Chinamen for a term of 6 years. It will be worked by the hydraulic process and a bedrock tunnel will be run immediately. The Grangers cannot interfere with this mine, as it has a dumping place independent of the Yuba.

MINERS ENJOINING MINERS.—Mrs. Hawk owns a gravel claim in the bed of a stream into which the tailings from the Hirschman hydraulic mines flow, and her son James says she will when the proper time comes, sue for an injunction to restrain the Hirschman company from covering up her mine with slickens. This is the best joke yet.

PLACER.

IOWA HILL.—Placer *Herald*, Nov. 12: J. B. Hobson, of Iowa Hill, favored us with a call while in Auburn this last week. While some of the hydraulic miners in that district are holding back owing to the slickens agitation, a majority of them have got, or are getting, their mines in order for active operations this winter. The drift mining outlook on the Iowa Hill divide is very encouraging. Many comparatively new locations have been made for over 20 miles up the ridge on what is believed to be the line of the extensive blue gravel channel, in which the Damascus or Mountain Gate Co. is operating. Gay has been struck in Greek claim and in the North Bassel, both believed to embrace portions of this same blue channel. The Giant Gap claim, a short distance above Iowa Hill, on which work has been prosecuted for years, and much money expended, has at last broke through the rim into the gravel, and has every prospect now of soon being ranked among the rich paying mines of that region. Quite a number of other claims, both gravel and quartz, are driving ahead their prospecting work, so that altogether the condition of the Iowa Hill divide is more than fair and its outlook particularly hopeful. Take away the stagnating effect of the debris agitation and that section of our county would be far more prosperous, and the scene of much more activity than has characterized it for many years.

THE RISING SUN MINE.—Colfax, last week end, was in quite a flurry over certain changes in the management of the Rising Sun mine. It is true that Supt. Werry resigned his charge of the mine, but other rumors to the effect that the men could get no pay we believe were not well founded, as it was the intention to pay up last Sunday. Why there should be any trouble is not easily understood, as our information, which comes quite direct, is to the effect that the mine made an exceptionally good run last month, and has fine prospects ahead.

PLUMAS.

ELIZABETHTOWN.—Plumas *National*, Nov. 12: No new developments in the Manson & Corbin claims this week, but the prospects continue flattering. The east drift from the lower shaft proves that the pay channel in the flat is over 100 ft in width, and the west drift shows good indications, and rich pay will probably be found in a day or two. The upper works are paying well, as usual, and the whole outlook is favorable. The work at the lower shaft has proved the channel much larger than the owners expected, and there is now no doubt but that it is extensive and valuable.

BROKEN DOWN AGAIN.—The boring machine in the shaft being put down by Mr. Mills, opposite town, came to a stand-still on Thursday, the auger being down about 07 ft. A few days ago the drill struck a rock, and some difficulty was experienced it getting past it. It is thought that the steel hand on the bottom of the pipe or tubing was broken, and since that time the lower end of the pipe has closed up until the tools will not work through it. This will make some delay, and probably make it necessary to sink another hole. The borer has so far been in fine looking, solid gravel, and should the big working shaft be pushed down, it is thought that no trouble will be experienced after the first 20 ft.

MONTE CURISTO.—Messrs. Smith and Parsons were in town on Tuesday and Wednesday, and from them we learn that operations are going on swimmingly up at the Peak. The snow fell during the late storm to the depth of about a foot, but has nearly all gone from the southern slope of the hills. Work is going along steadily, the main tunnel being now in some 2,500 ft, and progressing at the rate of 5 ft per day. The gravel in the face of the tunnel is improving in depth and quality in the last hundred ft, and but few large bowlders are now met with. The managers are much pleased with the indications, and think the outlook very flattering. Improvements are constantly being made. The work of sinking and raising an air shaft is being pushed as rapidly as possible, and it will soon be completed. A new boiler has been placed in the machine shop, of much larger size and capacity than the old one. The supplies for the winter have been received, and give some idea of the magnitude of the work. Probably 600 cords of wood are stacked up. In the storehouse is 20 tons of flour, 8 tons of vegetables, thirty hundred of butter, thirty hundred of beans, and everything else in proportion. The pay roll now shows about 40 names, but of course this is likely to be increased considerably at any time. Our informants seem to be in splendid spirits over the prospects of the Monte Cristo, and confidently look for grand success this winter.

SIERRA.

EXTENSION.—*Mountain Messenger*, Nov. 12: The Extension Co., has got a mule at work in its claims. The yield this week up to Wednesday noon was 34 ounces.

ANOTHER uptnise is being made in the Ruby tunnel at Caribou ravine.

ABOUT 300 cords of wood have been laid in at the Brush Creek mine, and work will be continued during the winter.

RAPID WORK.—About 50 men are at work on the quartz mill at Loganville. They will have it done before snow flies, probably.

TRINITY.

TRINITY CENTER.—*Journal*, Nov. 12: Several new houses have of late been put up in and about the Center and others are in contemplation. Johnny Coyle lately bought out his partner and is fitting up his claim in good shape. Powell & Carter, just above Coyle, have struck it rich, and in the adjoining claim below prospecting is being pushed with promises of soon striking it.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—*Enterprise*, Nov. 12: Are still opening out and repairing the drifts and winzes connecting with the old Con Virginia shaft. On the 2500 level the joint California and Con. Virginia winze has been sunk and timbered 5 ft, and are now putting in chairs.

UTAH.—Have completed work on the station and rock chutes and are cutting out a station for a blower. The east drift is extended 12 ft.

SIERRA NEVADA.—On the 2500 level cast crosscut No. 3 has been extended 50 ft, and No 5 was extended 27 ft. The east drill hole was advanced 155 ft. The main north drift was extended 30 ft.

UNION.—Are retimbering on the 1600 level in the drift connecting with the Sutro tunnel; are easing timbers on the 2000, and cutting out a bob-pit at the 2000 station.

UNION CON.—Are cutting out a station at the 2700 level of the joint Mexican east winze. The joint Sierra Nevada west drift has been extended 24 ft; the joint east drift has been advanced about 20 ft.

MEXICAN.—Are cutting out a station at the 2700 level of the joint Union Con. winze.

OPHIR.—Have completed the new line of compressed air pipe in the main lateral drift. The joint Californian cast drift has been extended 26 ft.

CON. VIRGINIA.—Are still opening out and repairing drifts and winzes connecting with the old Con. Virginia shaft.

YELLOW JACKET.—On the 3000 level the south lateral drift was run 27 ft, making the present length 147 ft from the switch. During the week we have timbered the whole length of the drift. The east cross drift is out 149 ft from the same switch, having been advanced 47 ft. The quantity of water pumped continues the same—58 miners' inches.

SUTRO TUNNEL CO.—The main tunnel repair men have placed in position 60 sets of new timbers in different parts of the tunnel, removed 70 sets of old timbers, besides repairing the track, clearing up loose dirt, removing rubbish, etc. Flow of water, 5,376,681 gallons.

BRISTOL DISTRICT.

MAYFLOWER MINE.—Piocbe *Record*, Nov. 11: Prodigious accounts are given as to the development of the large and exceedingly rich ore body in this valuable mine. As work progresses on the bonanza the bigger it grows, and the deeper it is sunk on the richer the ore proves to be. The mill of the company—a 10-stamper—let its stamps drop again last Sunday, and it is expected to clean up for the month of November somewhere between $60,000 and $90,000 worth of bullion. During the week, while in Bristol, Dr. Nichols picked from the teams hauling ore to the mill what he considered average samples and had them assayed, giving the following results: $537 24, $025 48, $223.00, $515 24, $225.21, $1,124 75, $653 47, $560.-68, $345.40. A fair showing.

CANDELARIA DISTRICT.

NORTHERN BELLE.—*True Fissure*, Nov 9: Since the last report a very encouraging strike has been made in the fourth shaft level. The development is in the west drift, and further in that direction than anything yet found in the shaft levels above. At present the ore shows a width of from 2½ to 3 ft, assaying from $60 to $310 per ton, most of the assay going over $100. This development is very promising, looking grandly, but sufficient work has not yet been done to determine its extent. The other shaft levels present the same appearance as at time of last report. The adit and levels above have shown no very material change during the week, though there is some improvement in the 9th. A few days since a change occurred in the formation on the 7th level, directly over the body of ore found on the 9th level, which looks promising to open into ore. There are being extracted and sent to the mills about 80½ tons of ore per day. Bullion shipments on Sunday will amount to $107,467.

MOUNT DIABLO.—The north crosscut from the bottom of the east drift, from the bottom of winze, No. 1, has advanced 7 ft into a ledge of low grade quartz ore, assaying from $20 to $26 per ton. The north crosscut from winze No. 3 is 85 ft in length; the face has shown small spots of ore for a few days past. In the intermediate level, below the third level, and between that and the bottom of winze No. 2, a ledge of good ore has been struck which assays $77. The north crosscut from the third level, and just above this body of ore, is also yielding considerable ore of a similar grade. The east drift has advanced 15 ft, and is in favorable ground. The winze from the east drift on the second level is down 40 ft; the stope from the west drift is up 32 ft. The winze in the gulch has attained a depth of 104 ft.

ESMERALDA DISTRICT.

A MILL AT LAST.—*Herald*, Nov. 9: There is no guesswork about it, for it is a settled fact—the Cortez mining company have a splendid piece of property and are going to build a mill. J. B. Hiskey has surveyed the mill site and set the stakes. The company have purchased the springs on Mt. Brady from S. G. Cobb and W. J. Vernon, and Mr. Hiskey the first of the week made a survey of the line of ditch from the springs to the mine and mill. The distance the water will have to be brought is 3¾ miles. It is estimated that at least 4 inches of water can be obtained at the dryest season of the year. The mill is to be built within a few ft of the mouth of the lower tunnel, and the cars from the mine will dump the ore right into the self-feeders. The mill will be a 20 stamp one, and Superintendent Wells informs us that it will be crushing ore by the first of June next. He went below Thursday to purchase supplies for the mine for the winter, also to contract for lumber for the mill and look at the latest improved machinery. Work is being pushed at the mine. The tunnel has been driven 30 ft this week, and the incline will be finished to a point on a level with the lower tunnel some time next week. The indications in the incline are favorable for a large body of ore on that level. The developments already made in the mine guarantee, at the lowest possible estimate, 60,000 tons of ore, and there is now on the dump 750 tons, taken out merely in running incline and drifts, that will mill from $150 to $200. This is a good starter for a 20 stamp mill and the boom that will strike our camp at an early day. The coal house is finished and J. F. Parker is hauling in 1,000 bushels of coal for winter use.

EUREKA DISTRICT.

PROSPECT MOUNTAIN TUNNEL.—*Sentinel*, Nov. 11: The *Sentinel* was informed yesterday that the whole face of the Prospect mountain tunnel is in a formation which, if not ore, is the very next thing to it. Bunches and seams of good ore have been encountered for the last 20 ft, and at last accounts the contractors were expecting with every blast to break through into a regular bonanza. The writer has thought that the tunnel would have to be run some 300 or 400 ft further to reach the main mineral zone, just west of the summit of the mountain, but in conversation the other day with a mining man who is entirely familiar with every inch of the ground, we were informed that there is a bend or swell in the lime belt, which carries it considerably down the hill in the direction of the tunnel. This being the case, the public need not be surprised to learn of an important strike in the west side tunnel at almost any moment. They are bound to strike it ultimately, and the only question is one of distance. The elbow in the line spoken of will hasten the discovery.

GOLD PARK DISTRCT.

REVIVINO.—Cor. Grantsville *Bonanza*, Nov. 12: Gold Park district is now attracting considerable attention and will soon come to the front as a producer of bullion. The town is located in a beautiful basin, nearly in the center of which is the Shoshone range of mountains, 35 miles from Grantsville, and about the same distance from Austin. This district was formed several years ago, and a number of mines located which were abandoned about a year after by the locators. Mr. Frank Bradley and others about 2 years ago relocated these mines, and after prospecting and working on some four locations about one year, bonded them to Messrs. Cooper and San Pedro, who are now the lucky owners, and who are at present actively engaged in developing two of them—the Arctic and Star of the West. The Arctic is a well defined vein, averaging 4 ft in thickness, carrying about $40 in gold and $20 in silver per ton. The Star of the West is not as large, will average about two and one-half ft, and the ore will mill $100 per ton in gold just as it is extracted, without any assorting. The company have commenced grading the ground for the mill, the material of which will commence to arrive in a few days. It is the intention of the owners to have the mill up and running by the middle of January, when the mines will speak for themselves.

KINGSTON DISTRICT.

OPERATIONS.—Eureka *Sentinel*, Nov. 15: D. O. Mahony, returned Saturday night from Kingston district, 30 miles south of Austin. The Victorine M. & M. Co. is carrying on extensive operations at that place. A 30-stamp mill and 2 O'Hara furnaces are in course of construction. The mine is rich in gold, the ore going from $40 to $1 000 to the ton. There is plenty of ore in sight. Seventy-five miners have been employed, and all of the stopes are filled with ore. The ore accumulated so fast that 50 of the 75 miners had to be dropped last week. Sweeney & Co. of Eureka, have three large quartz teams on the ground and the hauling of ore from the mine to the mill, a distance of two miles, was to have commenced yesterday. Large stables, etc., have been put up to accommodate the teams. The mill and one of the furnaces will soon be ready for business. The O'Hara furnace is something new in this State. Gasoline is extensively used in this process. S. B. Mowery, formerly superintendent of the Lemon mill at this place, has the contract for building the furnace. Kingston bids fair to become a prominent mining camp.

LEWIS DISTRICT.

DEVELOPMENT.—As the work of development proceeds the mines continue to improve, and the outlook for the permanency of the camp was never so good. New and important strikes are being made every few days. With the near approach of the end of the year, the numerous claim owners hestir themselves, and shouldering the ever-handy pick and shovel, wend their way to the promising prospect, there to do the necessary amount of work to hold what some day may astonish the country with its richness. New prospects will be discovered and located while this work is going on, and when spring arrives Lewis mining district will exp rience such a boom as has never been experienced since the days of White Pine. The mines are there. All that is needed is development, and that is going ahead as fast as money can send it. The Sunbeam, lately bonded by A. D. Couter, shows what development will do for a mere prospect hole. A short time ago it was simply a good looking and promising prospect. To-day it is one of the best claims in the district, and this with but a month's good work. Another instance is that of the G. W. Bothwell mine, recently located by L. B. Ball and Thos. Morgan. It was discovered by the opening of the railroad grade, a short distance from Middle Town. Although not opened up very much it already shows its worth. Ore from the grass roots assays $84 to the ton, and the promise of its developing into a splendid mine is excellent. The owners intend to put in a tunnel and open the mine in good shape.

SAFFORD DISTRICT.

ENCOURAGING.—*Silver State*, Nov. 15: Encouraging reports are received from Safford district. The Ouondaga mine is said to be producing ore that assays $300 per ton. The shaft on the Contention is down 65 ft, with a foot of ore in the bottom that assays $500 per ton.

ARIZONA.

SILVER DISTRICT.—Arizona *Sentinel*, Nov. 12: Work on a large scale is about commenced on the Amelia mine. This property, a short time since, was sold by Col. Coker to a Boston syndicate. They have a good ledge, and all that is wanted is development. Dr. F. W. Seward has returned from New York. Our affable friend is the representative of the Mendivil and Clip M. Co. He thinks of erecting a good custom mill at Norton's landing. The doctor is a thorough business man, and whatever he undertakes will be successful. Jose Seres, one of the first prospectors of Silver district, is in Yuma. Joe is enthusiastic in his praise of the ledges of this camp, especially the Black Rock mine, on which he has worked for some time past. Mr. Geo. Feick was in town this week. He reports everything prospering at Silent. Col. Frank Riggs, a prominent mining operator, will visit Silver district this week under the guidance of Mr. A. H. Cargill, of the Silver Glance mine.

BISBEE NOTES.—Tombstone *Epitaph*, Nov. 7: From Mr. J. C. Tappiner, who is developing some very promising mines in the great copper camp, it is learned that the Neptune Co. have commenced again to work the Uncle Sam mine, and have made a rich strike of carbonate of copper. This new find is about 200 ft northward from the old workings. The Atlanta has a tunnel running westerly, about 14 ft in length, in lime and oxide of iron, with a fair showing of striking ore soon. The new shaft of the Golden Gate is down 20 ft in fine carbonate and azurite of copper. It has improved steadily from the top down, and is looked upon as a good prospect. The Watsou mine is being worked, and turning out some fine silver ore. The Baton Rouge is down about 50 ft on an incline, and strikes occasional bunches of copper glance and sulphate of copper. It has two good walls, about 6 ft apart. From the foregoing it would seem that Bisbee is looking up, and will soon have other productive mines besides the Copper Queen.

SILVER BELT BULLION.—Arizona *Miner*, Nov. 11: The last run of the Silver Belt ore, made with the little furnace at the Agua Fria, during the month of October, amounted the nice sum of $24,000. This we consider good, when taken into consideration the diminutive size of the smelter and the annoyance of getting teams to haul coal with which to keep the furnace in blast. The Belt mine is, and has been, the best paying property in Yavapai county. To-day, at a depth of nearly 400 ft, the ledge matter is larger and richer than on the surface, hence we may claim for this property a permanency equal to the best prospected ledges in the country. Mr. Thorne, one of the owers, deserves especial credit for the manner in which he has clung to this property and worked it without aid from capitalists, but entirely upon the merits of the property itself. Tombstone, nor any other mining camp cannot boast of a mine superior to the Belt, of Yavapai. The smelter will continue in operation, and every day adds to the fame of the property.

GLOBE DISTRICT.—Cor. *Citizen*, Nov. 13: Peace and prosperity prevail here, and everybody appears to be encouraged and happy over the promising outlook for the future. The streets are thronged with people, all of whom seem busily engaged in every class of business. And the sidewalks are packed with new goods of every variety, and which continue to arrive daily by the tons. The machinery for the furnace of the Buffalo M. Co arrived on the ground yesterday and will be in place and ready for active operations in a very few days. The first shipment of bullion was made yesterday from the Miami mill. The number of ounces was not stamped on the bar, but it looked to be about $1,500, which is the first yield of Emeline ore to its present owners. From what we can learn the mine looks splendid and will be a constant producer of bullion from the present time hence. It is reported this morning that the 500 level in the Mack Morris mine has been reached and struck a vein of ore 22 inches wide of black sulphurets, that will run way up into the thousands of dollars per ton. The success of the Mack Morris mining enterprise is due absolutely to the experienced and intelligent management, without which there would have been ruin and failure long ago.

COLORADO.

PITKIN.—*Register-Call*, Nov. 11: Between 30 and 40 mines will be worked during the winter in the Pitkin district. Cummings & Flinn's smelter at Leadville, received a trifle over 500 tons of ore from the Adelaide mine during the month of October. The Evening Star and Morning Star since their consolidation have opened up splendidly. The output of the mines for the month of October was 2,600 tons, which brought an average of $40 per ton aggregating the handsome sum of $104,000.

DIAMOND.—The Diamond tunnel, near Georgetown, was driven 28 ft during the month of October, which made the tunnel on the 31st day of that month 1,756½ ft long, of 8 or 10 ft. A raise extends from the tunnel to the surface. They are stoping near the surface, where the vein is narrow, but it is a good one for its size. The ore will mill way up. A crushing will be put through the Gold Hill mill about Christmas. Allen & Oickinson have 8 or 10 men employed in the Yellow Jacket, half a mile northeast of the Gold Hill. They are taking out ore. One hundred tons are now on the dump. A tunnel has been run along the vein a distance of 200 ft, and 2 raises have been run up—1, 120 ft, reaches the surface, and the other has been carried up 130 ft, and is within a few ft of the surface. A connection has been made between the 2 raises, which are 30 ft apart. Good ore is being stoped out. A crushing will soon be made in the Gold Hill mill.

VIENNA MINES.—*Wood River Miner*, Nov. 13: We interviewed Chris. J. Johnson, who arrived from Vienna, in the Sawtooth country last week. He gave us some data from Smiley district. Mr. Johnson is stockholder in two companies, one organized at Winona, Minn., and the other at LaCross, Wis., and he is also superintendent of their mines. These companies own the Vienna, Mountain King, Hidden Treasure group, Alturas, Justice, Webfoot Oregon and others. These mines are located on the Sawtooth range, near the head of Smiley creek, about 90 miles northwest of Haley. Of these properties the Vienna is the best developed. Three tunnels show up this homanza. The first is in 190 ft, tapping the vein 150 ft from the surface; tunnel No. 2, 100 ft below, is run in on the vein 223 ft; tunnel No. 3, also on the vein, and 90 ft below No. 2, is in a distance of 300 ft; so any one can see that the mine is in splendid condition for extracting ore. The vein is 6 ft in width, and gives an average assay of 358 ozs. silver, and 134 ozs. gold. There are now 800 tons of this ore on the dump. Thirty tons were shipped to Salt Lake this year from which the company realized $311.05 per ton. A strong force will be put to work in this mine next year. On the east side of Smiley creek and opposite the Vienna is the King of the Mountain, which is developed by two open cuts across the vein, and a tunnel driven in 80 ft. In opening up this mine 700 tons of ore have been taken out and are now on the dump. This ore is free milling and averages 180 ozs. in silver. The Hidden Treasure group, extensions of the Mountain King, can be traced on the surface a distance of 2,000 ft, and are being opened up by two tunnels. This ledge has a remarkable width. A tunnel was run diagonally across the ledge a distance of 60 ft before the foot wall was found. The other mines owned by the companies have been prospected to some extent, and their dumps hold from 150 to 200 tons of high-grade ore. The companies above mentioned have located a mill site near the new town of Vienna, and about a mile and a half from the mines, and Mr. Johnson says they will take in a 20-stamp mill and roasters as early in the spring as possible, and next year give employment to a large force of men. The town of Vienna comprises about two dozen houses. Ten or 15 men will be employed there all winter erecting buildings for business occupation in the spring.

TEXAS DISTRICT.—Salt Lake *Tribune*, Nov. 0: Mr. Austin O'Toole brought to the *Tribune* office yesterday 1 of the most beautiful specimens of carbonate ore ever seen, from the Ainsley mine, Texas district. He reports 44 ft of the same kind with 60 tons on the dump. Texas district is about 16 miles north of Lemhi Junction, in Idaho. There have been from 80 to 100 miners at work in the district all summer, and the camp is most promising. Mr. A. H. Uhlig, owner of the McClellan, is expected here daily with several carloads of ore. Mr. O'Toole has several locations and reports the mines well defined and are as favorable for richness and permanency as could possibly be found. Next spring some smelters are to be put up there and "then," says O'Toole, "look out for more bullion to the ton than any other camp in Idaho ships."

MONTANA.

EMERALD AND GEM.—*New Northwest*, Nov. 11: J. K. Pardee, Supt. of the Algonquin mine, has leased the Emerald mine from Messrs. Ullery & Thomas, and has men busily at work constructing a whim and shaft house. He also secured the Gem mine and may probably open up a body of pay ore in it during the winter. He left for Helena last week on business connected with his new possessions.

THE Sharktown Tunnel Co. has struck the Scratch Awl mine in the granite. The vein is 7 ft wide and carries 4½ ft of solid ore, every pound of which can be profitably milled. They have about 35 tons now on the dump, the larger portion of which will go better than 100 ounces to the ton. The Algonquin Co. has secured the contract to crush this rock, and if present development continues favorable Murray & Durfee will keep the 20 stamps going steadily.

AT THE TROUT.—The main shaft is going rapidly down, the sump now being 540 ft from the surface. No ore is being stoped from the 400 level. A level will be driven at a depth of 560 ft, the vein crosscut and a new stope started, as the country rock in sinking has changed from blue to white limestone—an unfavorable formation. Every one interested in mining here, and especially in the Trout, is anxiously awaiting the next strike. Chris. Hart spliced the new cable Friday, and everything is reported as progressing favorably.

Smoke in Cities.

The Law Corporate Rights Explained.

An important decision has been rendered in this city by Judge Evans in the case of F. Hufschmidt vs. the California Street Railroad, the object of which was to abate a private nuisance and to recover $10,000 damages sustained by reason thereof. The plaintiff owns and resides in a house on the south line of California street, between Hyde and Larkin, which adjoins the railroad company's engine house. The plaintiff complains of the smoke, soot and cinders from the engine house and the commotion consequent upon the hoisting and lowering of the cars and dummies from the ground to the upper floors. It was not alleged that the defendant had been careless in the use of its works or that any injury complained of could have been prevented without stopping the use of the steam as an agency in operating the road. The only allegation in the complaint capable, in Judge Evans' estimation, of being construed as a charge of carelessness is the lack of sufficient hight to the chimney or smoke stack. The answer denied the alleged damage to the plaintiff's property, and sets up by way of excuse and defense that the erection of the works was authorized by certain ordinances of the Board of Supervisors, in pursuance of specific legislative authority. On the trial the plaintiff introduced evidence tending to show that his property had been injured and its occupancy rendered less comfortable, and then rested his case.

The defendant's counsel read in evidence the several ordinances authorizing the operation of its road, and offered to prove that all possible care had been used in so operating the line. The plaintiff objected to the offer on the ground that it was immaterial as to the amount of care used by the defendant, as it must at all events be responsible for the actual damages sustained by the plaintiff. This question as to the admissibility of evidence of the character in question was reserved for the consideration of Judge Evans, and further trial was postponed until a decision could be had. In a long opinion rendered, Judge Evans admits that the question presented to him for decision in this case is one of the greatest practical importance. If the plaintiff could maintain his action without alleging or proving negligence on the defendant's part, or assuming, as Judge Evans had, that negligence is to be presumed from the injury sustained by the plaintiff, and that the defendant cannot be allowed to rebut this presumption by the introduction of evidence such as that to which plaintiff objected, then it had necessarily to follow, argued Judge Evans, that all persons owning property in San Francisco and suffering from similar causes would be entitled to recover damages, and all furnaces, smoke stacks and steam engines within the city limits might be treated as private nuisances, and the business of all street railroads, factories and machine shops operated by steam power is liable to be destroyed, and this without regard to the legislative grants or franchises under which they have constructed and are operating their works, and also without reference to the amount of care exercised in the use of the motive power specially authorized by law. On the other hand, if the defendant can shield itself under the legislative sanction relied upon, the plaintiff and other persons similarly situated are without remedy, and the beneficial use of their property may be materially and permanently injured without any means afforded by the law of obtaining adequate relief. Thus there is suspended in the judicial balance scale, on the one side the luxury of pure air and individual comfort for the purposes of private dwellings; on the other, the necessities of modern civilization in the manufacturing, commercial and traveling world.

In Judge Evans' opinion, and in the light of the adjudged cases, the former must yield to the latter, and those who live in cities and populous centers, must forego the luxury of breathing pure air, uncontaminated by the dust, soot and smoke of the steam engines, and yield to the business necessities of the common herd in their daily vocations in the pursuit of bread; or, as was beautifully said by Lord Justice James in Salvin vs. North Brancepeth Coal Co., "If some picturesque haven opens its arms to invite the commerce of the world, it is not for this court to forbid the embrace, although the fruit of it should be the sights and sounds and smells of a common seaport and ship-building town." Judge Evans did not attempt to review in his decision all, or even any great number of decided cases, but he had examined carefully many of what appeared to be the leading English and American decisions upon the subject, and while they are not uniform, he was satisfied that the weight of authority is decidedly in favor of the views expressed in his opinion, and supported the conclusion at which he had arrived—that is, that where the Legislature has in express terms, either directly or through the delegation of power to a municipal corporation, authorized the construction and operation of street railroads by means of wire ropes laid under the streets and propelled by stationary steam engines, it must be presumed that the Legislature contemplated the consumption of coal and other fuel for the purpose of generating the requisite amount of steam; and that in doing so, soot, smoke and cinders would escape from the furnaces and be driven upon the property of private persons situated along the line of the road, to some extent injuring such persons in the comfortable enjoyment of their property; and that for such injury they can have no remedy, unless there has been a lack of the greatest possible care in the exercise of the franchise by the means so expressly authorized by law, such injuries amounting to the taking of private property for public use without just compensation, in the sense of the constitutional prohibition upon this subject. Judge Evans therefore overruled the plaintiff's objection to the introduction of the evidence offered by the defendant, which decision may be practically construed as a judgment for the corporation defendant.

Profit of Deep Gold Mines.

The following suggestive item is from the Nevada City *Herald* of the 15th inst.:

The handsome yield of $65,000 from the Idaho for the past month is an evidence that this mine is yet a storehouse of golden wealth, notwithstanding it has yielded over six and a half millions in the last 12 years, and there is every prospect that it will continue to yield profitably for many years to come. The ore which is producing so well and so profitably is mostly taken from the deepest workings of the mine, the 11th and 12th levels, where the vein is strong and uniform in its paying character. Two years ago there were apprehensions that the profitable days of the mine were drawing to a close, as the 10th level east ran into comparatively barren ground, in which the vein did not "live." Since then the No. 11 level has been opened and the drift carried under the barren ground spoken of, and a good-paying and well-defined vein found all the way. The No. 12 level has not been extended as far east as the No. 11, but it carries good ore in its stopes. The No. 13 level is now being opened, a drift having been run about 60 ft. The appearance of the mine is entirely satisfactory, and there is all encouragement to believe that it can be worked profitably to a much greater depth than has yet been reached. The new pumping machinery that provision is now being made for is in anticipation of much deeper working than has yet been attained, and when in place, which will be about the holidays, will be ample for all present and future demands. It is a cause for general congratulation, as regards the future prosperity of this mining district, that the Idaho is proving so profitable at a great depth, as it will be an encouragement for deep working in all of our mines, and tend to dissipate any theory that may be held that gold mines cannot be relied upon for profit at depth.

WAUCOBA.—J. Wal. Phillips and A. McKellips were in town yesterday from Waucoba district. The district is situated just across the summit of the Inyoe, nearly opposite Independence, about 30 miles distant. It was much talked of years ago, when Major Egbert, Dr. White and other members of Camp Independence organized a company headed by Alfred Bierstadt, the artist. Considerable money was spent on the property, building trails and making a great number of openings on the claims, but at no one point was any depth attained of consequence. A complete mill outfit was hauled in through Silver Peak and Eureka valley, from whence the machinery was packed over a mountain spur into the head of Saline valley, when operations ceased, and the works lie there yet. An active movement is now on foot in New York, whereby the Bierstadt M. and M. Co. are to resume active operations on the mines. Gen. Houston, with Prof. Fuller, an expert, is expected here shortly. The other company, recently organized in the East by Mr. Phillips—the Wancoba Con. Mining Co.—has Messrs. Phillips and McKellips at work there now. The chief mines are the Old Argentiferous, Great Eastern, Occidental, Oriental, Underwood, Truman Weed and the Lead Queen. The parties report the discovery of some very large ledges of argentiferous galena, and have no doubt whatever about their ability to show up sufficiently to justify the erection of a 20 or 30-ton smelter by next spring. The district abounds in water and forests of pinon wood, the only drawback now being the lack of wagon roads connecting with the head of Mezourka canyon. It certainly presents an inviting field for capital, and one bound to cut a big figure in the mining world.—*Inyo Independent.*

PLUCKY PROSPECTORS.—The Carson *Tribune* tells of two Germans—Klotz and Keizler—who have been prospecting a copper mine above the town of Genoa, and who certainly have shown no disposition to shirk hard work. It says: "Klotz and Keizler had no money nor mules, but they made a trail one and a quarter miles long, on an angle of 45 degrees, to the dump, and on their backs packed to the town of Genoa 4,600 lbs. of rock. The Lyon mill and mining company have offered $50 per ton for the rock, and a share of all it may bring over that amount. Our German friends will take the rock to Dayton in a few days.

DURING the fiscal year ending June 30, 1880, Idaho yielded $1,980,000 in gold and $450,000 in silver; during the year ending June, 1881, the yield was $1,141,652 in gold and $1,078,916 in silver; total for the two years, $5,020,568. The yield for the current year will probably be as large again as that for the past two years.

THE Central Pacific Company charges $5 per ton for carrying ore or bullion from Kelton to Ogden—a distance of 90 miles, while it only charges $10 to perform the same service from Kelton to San Francisco—about 800 miles.

Mining Rulings.

The following mining points were recently decided in the United States Circuit Court:

The act of Congress of May 10, 1872, authorizes a claim to be located 1,500 ft. in length along the vein, and in the absence of any local rules or custom, the width of such claim may be extended 300 ft. on each side of the middle of the vein; but said act of Congress, by implication, authorizes the miner to limit the width of such claims to 25 ft. on each side of the middle of the vein.

No rights can be acquired under the statute by location before the discovery of a vein or lode within the limits of the claim located.

A location is made valid by the discovery of a vein or lode at any time after the location, provided that such discovery is made before any rights are acquired in the same claim by other persons.

A vein or lode authorized to be located is a seam or fissure in the earth's crust, filled with quartz or some other kind of rock in places, filled with gold, silver or other valuable mineral deposits named in the statute. It may be very thin, or many feet thick, or irregular in thickness, and it may be rich or poor, provided it contains any of the metals named in the statute. But it must be more than detached pieces of quartz or mere bunches of quartz not in place.

A location of a mining claim must be definitely marked on the ground so that its boundaries can be readily traced; but the law does not define or prescribe what kind of marks should be made, or upon what ground or claim they shall be placed. Any marking on the ground claimed by stakes, mound or written notices whereby the boundaries can be readily traced, is sufficient.

The law of Congress requires no record of a mining claim, except in obedience to valid local rules or customs of miners, but when such local rules or customs require a record, it must contain the names of the locators, the date of the location and such a description of the claim by reference to some natural objects or permanent monuments as will identify the claim; but such natural objects or permanent monuments are not required to be on the ground located, although they may be; and the natural object may consist of a prominent post or stake firmly planted in the ground, or a shaft sunk in the ground. If, by reference to any such natural object or permanent monument, the claim recorded can be identified with any reasonable certainty, the record will be sufficient in this particular; otherwise not.

When one person or company owns several contiguous claims, capable of being advantageously worked together, one general system may be adopted to work such claims; and work done according to such system for the purpose of prospecting or working all such contiguous claims, although done on only one of such claims, or even outside of all of them, is available to hold all such contiguous claims intended to be worked or prospected by such general system.

The statute requires $100 worth of work on each claim located after May 10, 1872, in each year, and in default thereof, authorizes the claim to be relocated by other parties, provided the first locator has not resumed work upon it. But if the first locator resumes work at any time after the expiration of the year, and before any relocation is made, he thereby preserves his claim; the statute nowhere authorizes a trespass upon, or a relocation of a claim before located by another, however derelict in performing the required work the first locator may have been, provided he has returned and resumed work, and is actually engaged in developing his claim at the time the second locator enters and attempts to secure the claim.

GREAT SALT LAKE.—One of the wonders of Utah is that of the Great Salt lake. At present it occupies a space of about 3,000 square miles. The greatest length is 93 miles, while the greatest width is 43 miles. Several large islands rise to great hights above the surface, the largest of which is over 30 miles long, and in the widest place about 12 miles across, and it is mountainous in its character, with streams of water, forced by springs and drainage, flowing through the ravines and canyons. On this island, which is called by the name of "Antelope" or "Church island," ranchmen raise herds of horses, cattle and sheep upon the rich land found there. The other islands, of which there are several, are small, and inhabited by loons and seagulls. The flow of waters into the lake from the rivers Bear, Weber and Jordan, and of numerous streams, from actual measurement, is over 6,000 cubic ft. per minute—a quantity sufficient to cover the lake in one year to a depth of 40 inches; but the evaporation is so great in this climate that the great influx is overcome, and the lake remains much the same in hight from year to year. In the spring the water is some inches higher than at any other period. The greatest depth of water fathomed is 60 ft. While the waters of the sea contain about 2% of salt, the waters of the Great Salt lake contain about 22%, or about one-fifth of the bulk. During the summer season the lake water becomes warm, and makes an agreeable and invigorating bath.

NEWS from Altar, Sonora, says that trouble is brewing between American mining companies and Sonora merchants. The latter, it is said, are endeavoring to stir up litigation for the companies, and are coercing the judiciary to aid in their schemes.

Working Tailings.

Last Tuesday we paid a visit to the mill erected by the California Water and Mining Company, at Greenwood, for crushing the tailings from the celebrated French claim, one of the "seam diggings" for which the Greenwood section has been renowned. The mill is a spacious and commodious structure, well arranged and admirably conducted by the present Superintendent of the mine, William Powning, of whom more anon. The mill is run by water-power. The pressure is 200 ft., acting on a nine-foot hurdy-gurdy designed by Mr. Powning. They work it up to about 35 horse-power, and run 4 Huntington batteries (equal to 20 ordinary stamps), 2 rock-breakers (Dodge's patent), 10 concentrators, 2 Knox pans, 1 Atwood amalgamator, and 1 Huntington amalgamator, which latter, with the improvements Mr. Powning has made, is "the boss" amalgamator, at least for the kind of work required of it in that mill. At an expense not exceeding $15 per day Mr. Powning runs the whole business and puts 40 tons of tailings through the mill in 12 hours, or 80 tons at corresponding cost in 24 hours. The body of tailings to which this mill is easily accessible is so enormous as to be almost incalculable, but we feel safe in estimating that there are enough of them to keep 100 stamps running for 20 years. At first these works were placed in charge of a theoretical chemist, who had nothing practical in his composition, and they did not pay. But under Powning, who is not only an experienced, practical miner, but a thorough mechanic and an inventive genius as well, ever on the alert to observe and learn, a man in whom high qualities of brawn and brain are happily combined, the enterprise has become self-sustaining, and it has become a clearly demonstrated fact that by sufficient increase of crushing capacity it can be made to pay enormously. For, even if our estimate is extravagant as to the amount of tailings that is available, it has become quite clear that, after these are disposed of, new supplies can be obtained from the original "seam diggings," which will pay a good deal better than the tailings. We hope and expect in the near future to see at least 20 batteries at work in lieu of the present outfit of 4, when we think that this will be one of the most profitable mining enterprises in the county, and when they get to work on the seams with this increase of crushing capacity we predict results that will appear fabulous.—*Montana Democrat.*

Strike in the San Diego Mines.

From Mr. George V. King, who has just returned from a trip to Julian, we have the following account of the development of an exceedingly rich ore body in the Ready Relief mine of that district. About four weeks ago, at the depth of 350 ft., a ledge was struck which showed very fine ore, and work has since been quietly carried on in the opening of it up. Mr. King, (who is one of the original owners of the Chariot mine), says that the best development of the Chariot was nothing to this. He regards it as the most important strike that has been made in the district. He exhibited specimens filled with gold, and says that one can go with a candle along the ledge for 150 ft. and see similar ore all the way. The development of such a magnificent ore body, at this depth, proves what the *Union* has maintained from the beginning, that the mines of Julian are not mere surface pockets, but permanent ledges, which will grow richer as they are penetrated. The ledge now opened is from two to four ft. wide, the width increasing as it dips downward. It is the most extensive and richest ore body yet opened in the Julian district. Fourteen men have been employed in the mine, but the force is to be immediately increased, the work being pushed night and day. The Ready Relief mine was discovered in August, 1870, by D. D. Bailey, who sold it in 1874 to Adnah Neyhart, of Pennsylvania. Mr. Neyhart put up a fine 10 stamp mill and resided at the mill for some time. During a visit to the East about six years ago he died. About a year ago Mr. Bailey and Mr. Baruch, of Los Angeles, bought the mine from the administrator of his estate, and have since been actively engaged in its development. They may be congratulated upon the ownership of one of the most valuable mining properties in California.—*San Diego Union.*

MEADOW LAKE.—The most romantic town on the coast, says the Truckee *Republican*, is Meadow Lake. It is close up to the summit of the Sierras, near a beautiful lake. It grew up in one summer to be a great town. Thousands of people put thousands of dollars there. There was plenty of gold, rich gold ore there, but the gold had a terrible liking for the rock, and nobody could get it out. A few stayed the first winter. The snow fell 20 or 30 ft. deep. The people made tunnels from one house to the other and contrived to get through the winter. The only way in and out was on snow-shoes. The next spring everybody ran away, and the town collapsed and fell down. Adventurous parties have every year tried to work the ore, with very little success. Walter Hemilton, of Oakland, a mining expert, now comes to the front and claims that he has discovered a process by which the rebellious ores of this district can be worked successfully at a cost of $1.50 per ton, and if he can do so, Meadow Lake will soon become one of the most important mining districts on the coast.

Stampede Gap.

A correspondent of the Pioche *Record* says: My predictions of a few weeks ago as to the large deposits of mineral contained in this section, and the development of the same at no distant day, are rapidly becoming realized. Within the past few weeks there have been two valuable discoveries made here, one by that energetic and veteran prospector, Mr. Simpson, and the other by Mr. Short, formerly foreman of the Bullionville furnace, and his mining partner, Mr. McDougal. Mr. Simpson's claim lies at the base of Stampede hill, and close by the Bristol road. The ground in the neighborhood of the mine has been prospected at different times for years, as there has been very rich float found within a few feet of the late discovery. The formation is blue lime and granite, and therefore a very rich quartzite. Samples teeted in Pioche went from 6 to 800 ounces in silver per ton. The ledge, as I write, is about eight inches in width, with every indication of the ledge widening as depth is attained. In view of the promising outlook of his mine, Mr. Simpson is building himself a house close by, and as he casually remarked the other day, "I am going to stay by this one, you bet!" It seems that the old gentleman was at one time part owner in the since famous Standard mine of Bodie, Cal.; but, like a good many other excitable prospectors, was lured away to the new El Dorado in Arizona, much talked of at the time, but never found. Messrs. Short and McDougal's new find is on the slope of the hill, and near their iron mine. A sample taken from the croppings, and assayed by Mr. Vallejo of Bullionville, went 156 ounces per ton, which is undoubtedly very good encouragement to these gentlemen to work the property.

In my peramhulation through the hills a few days ago, I visited some of the prominent mines around Highland. The Anderson mine, in my opinion, is a valuable property, and one that would materially help this section if it were in the hands of parties capable of developing it in a proper manner. As it is, Mr. Anderson is realizing quite a sum by his own labor, having within a month filled 15 sacks with ore that will average $3,500 per ton, besides shipping to Bristol several tons of a lower grade. I next visited the Magnolia, situated a few hundred yards below on the same hill. It is owned by Mr. Anthony McMahon of Bullionville and a Mr. Lee. It is one of the most promising prospects that it has been my pleasure to see in a long time. They have a very nice shaft sunk on it to the depth of 68 ft., with a four-foot vein of a high-grade chloride, and several tons of the same quality on the dump ready to ship. Truly, it is better to be born lucky than rich in this very uncertain world of ours.

From the very favorable accounts at hand from the Jackrabbit, Mayflower, Mendha and other mines, it is safe to predict a mining boom of no small dimensions in Lincoln county this coming winter and spring, and the revival of the flush days of '72 and '73, so dear to the memory of the old-time Piochers.

Electric Light-houses.—A proposition is before the French Government for the establishment of 67 additional electric light-houses on the French coast at points where they will render the greatest service. It is believed that, with this number and the increased volume of light from the present more perfected lamps, the dangers to vessels will, as far as the French coast is concerned, be obviated. A similar demand is before the English Government for the establishment of 60 additional electric light-houses, and the necessary amount for their construction has been asked for from Parliament. In the United States also the necessity of the establishment on an equally large scale is being considered. The Turkish Government is studying a plan for the creation of an electric light-house system for the coasts of Turkey. The utility of electric light-houses would seem, therefore, to be universally acknowledged.

Cleaning Up for the Winter.—At the Omega tailings mill, Six-mile Canyon, they have commenced cleaning up preparatory to shutting down for the winter. The tailings mills down on the Carson river, however, are able to run all winter, as the snow does not there accumulate on the reservoirs and dumps to such a depth as to give trouble.

There is a great sensation in Lewiston, Idaho, with regard to new diggings on Salmon river. A wing dam put in near Elk creek for prospecting purposes turns out to be an immense success. Two thousand dollars have been taken out by one party in 24 hours. Machinery has been ordered from Portland to work on a large scale.

More Power to 'Em.—The water from the Alta shaft is now being carried up Gold canyon so far as to bring it above the water wheels of the Spanish, Moyle and McGinley mills. This will greatly add to the efficiency of said mills. The top of the Alta shaft is sufficiently high to allow of the water from it being sent up the canyon nearly to the central part of Gold Hill.

The Brunswick mill, Carson river, is running on tailings, reducing about 120 tons per day; the Morgan mill is running on Crown Point and the Vivian ou Belcher ore.

Useful Information.

Cleaning old Engravings.—If brown spots and rings of mildew have not made their appearance, float the engraving face downward for 24 hours on a large quantity of water, in a vessel, perfectly free from grease and soil of all kinds. Lift it from the water on a perfectly clean sheet of glass, drain, transfer to blotting paper without touching it, then transfer to fresh blotting paper, dry, rub with bread as is done in drawings, and iron. If the stains are bad, or are not removed by this plan, place the engravings in a shallow dish, and pour water over them until perfectly soaked. Carefully pour off the water and replace it with a solution of chloride of lime (1 part liq. calcis chlorate to 39 parts water). As a rule the stains disappear as if by magic. If not, pour on the spot pure liq. calcis chlorate; if that does not succeed, add a little acid nitrohydro-chlor. dil. As soon as the stain disappears, wash the engraving carefully with successive portions of water until all the chlorine is removed. Then steep it in a weak solution of glue and gelatine, which may be colored with coffee grounds, to give the engraving a yellow color. Then dry between blotting paper, under a weight, and iron with a sheet of clean paper between the iron and the print. Small grease spots may be removed by putting powdered French chalk over them, a piece of clean blotting paper over the chalk, and a hot iron over that. If the stains are larger, benzine must be used, applying it in a circle around the stain before touching the stain itself.

White Lead.—Mr. G. J. Lewis, of Philadelphia, proposes to obtain white lead by beating the fumes of lead resulting from smelting processes, and then passing it into a cooling retort. Finely powdered sulphuret of lead (galena) is introduced into a funnel, whence it is forced by a bellows into the retort. This retort is heated to a red heat, which causes the sulphuret of lead to sublime and to deposit itself on the cooler surfaces. The fumes of lead then pass into a cooling chamber, and finally into a reservoir where the product is collected. Another method of obtaining white lead is to introduce sheet lead into a chamber containing jars of acetic acid, the atmosphere being heated by steam to a temperature of from 30° to 50°, besides being strongly impregnated with carbonic acid.

A New Feminine Necessity.—Among the latest Parisian novelties is the advent of the paralune as a supplement to the parasol. The rays of the moon are quite as dangerous as those of the sun, say the chroniclers of the novelty. One can be moonstruck just as one can have a sunstroke. If the sun browns the skin, the moon dries and wears it out, just as it affects the surface of stone. Therefore, the ladies who are staying at country houses where long country walks at night are often arranged, that one may enjoy the moonlight, should remember to secure one of the dainty paralunes made in gauze, lined with red silk, which are declared to be the last effort of fashion.

Nickel Table Utensils.—Since the process of making malleable nickel has been perfected, many articles made of this material, and especially nickel table utensils, are coming into extended use. They are manufactured in large quantities in Prussia, and are much preferred to similar articles of other materials. The hardness of the metal renders it capable of acquiring a high polish, which is not readily injured by friction; grease or dirt does not adhere to it firmly on account of the smoothness of its surface, and the cleaning requires very little exertion. It does not tarnish when used frequently, and has, moreover, the advantage of possessing about one-half its original value when worn out.

An Electric Letter Carrier.—Dr. Brunner, of Wattenwell, Austria, has invented an electric letter carrier, in the form of an underground railroad moved by electricity. The invention is at present before the Austrian Society of Engineers for inspection. The locomotive can be guided and controlled from a stationary point, because the battery or motive power is not on the locomotive; it does not need any accompanying attendance. The locomotive and train can be constructed of any diminutive size, and both will perform the same service for any length of distance which the pneumatic tube will perform for short distances.

Stove Polish.—The fine polish given stoves by those skilled in the art, is produced as follows: Have a thin mixture of black varnish and turpentine; apply this with a paint or varnish brush to a portion of the stove; then with a cloth dust this over with pulverized British luster or stove polish; then rub with a dry brush. The stove must be perfectly cold. The stove dealers buy the pulverized stove polish, which is carburet of iron, in 25-lb. packages. The process conducted in this manner is quite brief, but gives beautiful results.

To Make Cisterns and Tanks Water Tight.—Paint thickly on the inside with a mixture of eight parts of melted glue and four of linseed oil, boiled with litharge. In 48 hours it will be so hard that the tank can be filled with water.

What Is Linoleum?—A contemporary answers as follows: We have been informed by what we regard as good authority that it is made by covering strong jute cloth (burlap) with a mixture of linseed oil and cork powder, to which some mineral color has been added, to form a ground on which the pattern is subsequently printed. The general process of manufacture is doubtless identical with that of oil-cloth. With respect to the wearing qualities of linoleum, we can speak from personal knowledge in terms of the highest praise. The material is elastic, accommodating itself readily to the irregularities of the floor on which it is laid, and is not liable to crack when laid down on a rough or uneven floor. In this respect it is greatly superior to oil-cloth, which is notoriously troublesome in this particular. This same quality—due, no doubt, to the elastic nature of the cork it contains—gives it excellent wearing qualities, in which respect also it is decidedly superior to oil-cloth. It will bear the roughest usage, and almost completely deadens the noise of footsteps. The material is, without doubt, excellently adapted for its intended use, and has come to be very generally introduced as a substitute for oil-cloth.

Cotton and Straw Dwellings.—At the South, it has been demonstrated that fire and water-proof houses can be built out of straw. The cotton used is the refuse of the plantation and factories, and when ground up in about an equal amount of straw and asbestos, is converted into a paste, and subsequently into large slabs or bricks, which become as hard as stone. The article thus made is pronounced the best of architectural material, and will be much used.

A beech railroad tie, it is said, if effectually preserved from rotting, is better than white oak. Elm, black and white ash, if effectually preserved, will hold a spike about two-thirds as well as beech or oak, and one-third better than chestnut. Soft maple and sycamore hold a spike about four-fifths as well as chestnut, about two-fifths as well as oak or beech, and about one-half better than hemlock. Seasoned white oak is about one-third less effective than green timber in holding a spike.

Lime Bricks.—Among the patents issued in September last, was one to Jacob Rsese, of Pittsburg, Penn., for making lime brick. The method consists in burning and indurating lime or limestone at a high temperature, then grinding it and mixing it with water charged with silicate of lime until it assumes a plastic condition, and then molding and burning the brick in the usual manner.

Good Health.

To Avoid Epidemics.

In a state of health there is a certain degree of *excitement* in the system. This is, the pulse beats a certain number of times every minute, averaging about 68. If, during the cholera or any other ordinary epidemic, the pulse does not go below that, and the general system is in good working order, the disease does not attack the person, nor will it as long as he remains in that condition. Nor will he be likely to suffer from the epidemic if he keeps the system steadily above the natural excitement. But the very moment the pulse is below par in rapidity and vigor, that moment is the individual more liable to disease in proportion to the deficiency. A person in good bodily condition, then, is at par, and is not likely to be attacked by any ordinary epidemic disease; and if in that condition he take a glass of brandy, he is less liable still, until the exciting effects of the liquor have subsided, when he falls below the natural standard, just as far as he was a while ago above it, and is in proportion more liable to the disease than if he had taken no brandy at all. Therefore, having commenced taking brandy, he must keep it up day and night, never letting the system go below par, or he is a lost man. Hence it was that men who were always full of liquor escaped cholera in numerous instances, and the report went forth that brandy prevented cholera; thus multitudes were introduced into the wretched habit, and perished in a drunkard's grave.—*Journal of Health.*

Shampooing.—When the barber kindly informs his patient that his hair is very badly filled with dandruff, and proposes to shampoo it as a remedy, it is safe to say "No," most positively; the majority of barbers use as a shampooing liquid, either solution of "salts of tartar" alone, or mixed with borax. They are probably not aware that "salts of tartar" is but a name for purified potash. When a solution of this is put upon the head it combines with the natural oil of the hair and scalp, and forms a soap which makes a dense lather in the hair; this is washed out, and while it effectually removes the dandruff and dust, it has also removed the oil which is needed to keep the hair in a healthy condition. Avoid all such shampooing. A teaspoonful of powdered borax in a quart of water forms a safe shampooing liquid, but still better is the yolk of an egg, worked thoroughly into the hair, applying a little at a time, and then wash it out. The egg will leave the hair surprisingly clean, and the scalp soft and free from dandruff.—*American Agriculturist.*

Benefits Derived from Washing in Cold Water.

As in most things, so in washing, there are two ways of doing it. Some people take a bath who have but a dim idea of washing themselves, and are vexed and annoyed when told the result is not happy.

It is a well-known fact, but rarely remembered, that the skin is one of the great safety-valves of the human machine—that the millions of little perspiratory tubes with which it is pierced throw out from the inner body an average amount of 33 ounces of greasy refuse and worn-out material in an hour, in the shape of invisible perspiration and in the same time often as much as two or three lbs. in visible perspiration. Should these tubes or pores be allowed to remain choked with their own secretions, the refuse matter is thrown back into the other great corporeal scavengere—the lungs, stomach, liver or kidneys. Thus it stands to reason that a careful and general cleansing of the skin is absolutely necessary to the life and well-being of the individual at least once in 24 hours, and few people who rejoice in the comfort of cleanliness will feel that it is secured under this amount of washing. And we should also here point out the mere passage of water, especially cold water (*e. g.*, what is ordinarily called a sponge bath), does not cleanse. In fact, it rather has a tendency to close the pores, which, like delicate flowers, shut up to a cold current of wind or water. We therefore recommend, as warm or tepid water tends to open the pores, to use that with the course of soap scrubbing (not an unreasonable friction) which should precede the universal sponging. This last may be done with cold water, which certainly invigorates and braces the system when followed by a reactionary glow of warmth. Should this not occur it is unwise to use it, and warm must be substituted, especially in the case of children, who by ignorant mothers are often forced into cold water (from which they have not a sufficiently active circulation to recover) as part of that much-abused system of "hardening," which, nine times out of ten, ends in "hardening" the child off the face of the earth, or checking its growth.

"Hardening," it must be understood, should be strengthening, not "roughing," and many people with the best intentions think, very erroneously, that to make a child strong consists in causing it to undergo more physical hardships than they, with their perfectly matured strength and age, would dream of doing.

As people, in conclusion, generally rush to extremes, it might be well here to remark that we do not at all recommend coddling; but no wise mother will put her young children into quite cold water in winter time, nor with a cold, and, above all, will never allow them to be washed and bathed in a draught, on the same principle of consistency that plenty of fresh air is good, when it is not damp or foggy, but drafts are most injurious.—*Journal of Health.*

How to Grow Beautiful.—Persons may outgrow disease, and become healthy, by proper attention to the laws of their physical constitutions. By moderate and daily exercise, men may become active and strong in limb and muscle. But to grow beautiful, how? Age dims the luster of the eye and pales the roses on beauty's cheek; while crow-feet, and furrows, and wrinkles, and lost teeth, and gray hairs, and bald head, and tottering limbs, and limping feet, most sadly mar the human form divine. But dim as the eye is, as pallid and sunken as may be the face of beauty, and frail and feeble that once strong, erect and manly body, the immortal soul, just fledging its wings for its home in heaven, may look out through these faded windows as beautiful as the dewdrops of a summer's morning, as melting as the tear that glistens in affection's eye, by growing kindly, by cultivating sympathy with all humankind, by cherishing forbearance toward the foibles and follies of our race, and feeding day by day on that love to God and man, which lifts us up from the brute and makes us akin to angels.—*Journal of Health.*

Vaccination.—It is strange that so many persons declare their want of faith in the virtues of vaccination, when volumes of proof might be produced to prove its efficacy in preventing the attacks of small-pox. The greatest mortality from this disease has always been found in localities where vaccination was refused or neglected. In Chicago it is stated that 40 % of 359 cases since January 1st have proved fatal, and a large proportion of the fatal cases have occurred among the populations who resist vaccination with violence. Eighty-one out of 108 deaths from small-pox in September were in a ward where there are 40,000 persons who have not been vaccinated. This is but the repetition of a story that has often been told with much more melancholy details. Vaccination costs little or nothing, but as it is well established that it is, in a large majority of cases, an effectual preventive of small-pox, those are to blame who refuse to try it.

Dog Meat.—Robert Bloakie, who has just died in Wabash, Ind., had for nine years lived chiefly on dog meat, which he declared to be wholesome and palatable. His family relish the same food, and propose to continue its use.

Another electric railroad will soon be opened at Berlin. Siemans and Halskie have apparently made a success of the experimental one noticed previously.

Delinquent Sale Notice—Newcastle G. M. Co., S. F.

Passing Events.

A convention of miners and farmers was to have been held in this city this week, hut, owing to the fact that the Gold Rnn case is now going on in Sacramento, the convention was postponed nntil the conclnsion of that case. The testimony taken this week np to this day (Thursday) has been mainly from J. N. Hoag and J. M. Hoagland, as to knowledge of the Sacramento and American rivers since 1849, and to the damage done hy the deposits of slickens. Hoagland testified to much the same as Hosg. Counsel in the cese are: For plaintiff, Attorney-General Hart, George Cadwalader, ex-Chief Jnstice Rhodes and I. S. Belcher; for the defense, S. M. Wilson, ex-Chief Jnstice Wallace, W. C. Belcher, J. K. Byrne, A. B. Dihble and A. P. Catlin. There are engaged on the case six phonographic reportere, and the witneeses are nnmeroue. The case will prohahly last 10 days.

The Sheriff has this week again vieited the hydraulic mines in Nevada county. At all the mines vieited no work was being done, and in eome of them water was not even rnnning. Owing to the reeignation of R. McMurray, late superintendent for the Enreka Lake Co., no superintendent or managing agent for that company conld he found, and the Sheriff was ohliged to serve the notice hy posting it on the company's office. The China Co. at Moore's Flat were served in like manner, bnt in the rest of the mines the superintendents or foremen were found.

This week's PRESS will he fonnd to contain several valuable articles to the miners of the coast and to the mechanics also. To the lstter Mr. Richard's lecture on "Constrnctive Processes" will prove of interest, written as it is by an eminently practical man.

We have eent this week a representative of the PRESS to Arizona to sesrch out for ns all the matter of interest he csn find in that region which will he of interest to our readers.

The fact that the mines of thie country produced during the year 1880 over $87,000,000 in gold and eilver, actnally recorded hy mint statements and transportation companies records, is an item worthy of conaideration hy thoee who still lshor nnder the impression thst this industry has made no return for the grest outlny thst its successful working requires. In addition to this snm of money, added to the indestrnctihle weslth of the conntry, there is a large prodnction of which no record can he kept, as a large proportion of onr mines are worked hy private parties and companies, which amonnt we are inclined to estimate nearly, if not qnite, equal to the recorded ontput.

The Garfield Shaft.

The Quickeilver Mining Co., New Almaden, Santa Clsra county, are sinking a new shaft which is called the Garfield shaft, in honor of the late President of the United States. The manager intends making it a model piece of mining work, worthy of its namesake in every respect, inclnding the machinery for nperating it.

Mr. J. B. Randol, the manager, has sent a memorandnm to the fonndrymen of this city, regarding the work the company desires to perform, asking them to submit for approval, plans and estimates for an engine or engines with steam generators, all so designed as to do the required work in the hest and most perfect and economical manner. Fuel at the mine is expeneive (coal, a ton of 2 240 lbs., $12, aud wood $7 a cord), and it is desirahle to work stenm to as great a degree of expaneion as poseihle.

The requirements for the hoisting outfit in the new shaft sre ae followe:

Skip, weight, 1,700 lb; ore, weight, 3,000 lbs.; round steel rope (1,800 ft.), 2,900 lbs.; speed of skip per minute, not less than 600 ft.; nnmher of loads daily, 200, of which 140 may be taken as ore, and 60 as men and materinls. One hundred loads of ore are to he raised in 12 hours.

The greatest depth of shaft will be 1,800 ft.; a level at every 100 ft., commencing at 600 ft. from the surface.

The engine is to combine, so far as possihle, maximum of expansion, maximum equality of motion, and the greateet compectness, strength and cheapness, not only as regards the engioe itself, hut with regard to the engine-house and fonndations.

The hoisting gear to he nsed, is to he such es to employ the engine to the heet advantage, and to he perfect in every respect. The drums and pit-head pnlley are to he not less than 10 ft. in dismeter.

As soon as the contract for this machioery is awarded, we shall publish the details of the plans selected.

The Debris Convention.

The convention of miners snd farmers which was to have met in this city on Thursday, wns postponed, pending the trial of the Gold Run case, at Sacramento. A few daye since, the farmers of the Anti Debris Association bad thonght that they would hardly be prepared to send their delegates on Thursday, hnt at the reqnest of Mr. Hawley, President of the Debris Committee, had decided to send them, even if the time desired for their selection was not allowed. Then came the reqnest of Mr. Hawley, although that gentleman stated that the miners would send delegates if the farmers opposed the delay. The Gold Run case had heen called, and as it had several timee heen continued, Judge Temple insisted npon its hearing, and it was thought that it wonld occupy at least two weeks. President Sexey, of the Sacramento Valley Anti-Debris Association, agreeing to a delay, the meeting of the convention was continued without day.

Mr. Gordon, Secretary of the Debris Committee of the Board of Trade, is in receipt of numerons letters from the interior commenting upon the report of the committee published last week. He says that every miner, whether of large or small intereet in the subject, that hae written or conversed with him, ie pleased and perfectly satisfied with the report of the committee. On the other hand, he says he has yet to meet or hear from the first farmer or land owner who is willing to admit their satisfaction, hut rather complain that the committee did not go far enongh in their recommendations. The farmers are ready and willing, however, to attend the convention proposed in the committee's report. The miners are aleo as desirous to participate in the convention, and only ask a delay in calling it until after the great mining suit now on trial at Sacramento is ended, as many of the pereons they desire to send to that convention are engaged in that trial. Mr. Gordon states that the convention will he called at the earliest date consistent with the miners' request.

An Appendix to "Testing and Working Silver Ores."

By C. H. AARON.—*

Since the above hook was published certain facts hsve heen observed with which it is proper that those who hsve purchased it should he acqnainted.

Crocker's trip-hammer battery and Kendall's oscillating hattery hsve been condemned for want of durahility. Noyer's pulverizer does not appear to have come into use. Aaron's amslgamator hee not been constructed on a lsrge ecale. The vacuum chamher for leaching apparatus No. 1 hss heen found inferior to pumps. The leaching apparatus No. 2 hae not heen tried. The apparatus deecribed for drsining a portion of the water from wet-crushed ore, and avoiding the necessity of shovseling the pnlp out of settling tanks hae not heen tried, hnt the writer still thinks it worth trying. Something similar has been used with success.

A rock-breaker and a pulverizer on a new principle, have been invented hy W. C. Morieon, nf thie city. The same principle is applied in hoth. The device is eimple, yet its action in crnshing ore is complex. An idea of it may he formed hy supposing a coffee mill, of the kind which is mounted on a small hox, to have its crushing surfsces smooth instead of corrugated, its outer cone revolved hy gearing or helt, its inner cone free to rotate on its axis, and thie axis *slightly oblique to that of the outer cone.* The laet point is that which makes this essentially a *crushing*, not a grinding mill. The two axee, intersecting at a point near the bases of the cones, diverge towards their upper ends. The result of this arrangement is that a horizontal section at the hase of the outer cone shows an outer circle inclosing an inner ovoid which is practicslly a circle, concentric with the outer circle. A section at any point above the hase would show two eccentric circles, the one within the other, the eccentricity, ae well as the interval between the two, increasing as the section is further removed from the haee. If a piece of rock be placed hetween these circles at the point of greatest interval, and the outer circle he made to revolve, the rock, pressed against the inner circle, canses that to revolve also. The rock is thus carried into a narrower epace, and crushed with greater force, until, having pessed the narrowest point in thie zone, the fragments again coming into a wider space drop to a lower zone, nre egain carried around to the narrowest point in that zone, and again crushed, and so on until they emerge at the base of the machine either as small fragments or ns a fine powder, according to the adjustment.

The theoretical merits of the device are remarkahle, and there is no apparent reason why they shonld not he realized in practice. The action is eseentially crushing hy compression, continuous in a general sense, yct intermittent ae to any particular piece or set of pieces of rock. At the same time the conditions are euch that it is impossihle for any two points in the crushing surfaces to remain opposite to each other for more than an instant of time. There ie thus a slight hut constant grinding in hoth a vertical and horizontal direction. This peculiarity is likely to prevent the surfaces wearing in grooves or depreseions. The plane of rotation of any given zone on the surfnce of the inner cone heing obliqne, tends to carry the rock downward while crushing it against the horizontally revolving onter cone. This assists the discharge. The machine ae a breaker ie free from the tremendous shocks to which a Blake or Dodge is exposed, heing in fact a machine of "constant contact" if continuously supplied with rock.

I have epoken of cones only for convenience. The crushing surfaces are really in hell form, more especially so in the pulverizer, in order to give it sufficient capacity for dischsrging. A pulverizer on this plen has, ae I have heen informed, heen at work for a numher of weeks in Amador, giving great eetiefaction, and though only some 18 inches in diameter, doing, it is said, the work of a 10 stamp hattery. It is presumable that the ore is first passed through an ordinary breaker, as the breaker on this principle hae not yet heen conetructed. The machines will work either dry or wet, and there is a prohahility that even damp ore will psss through them hetter than through eny other pulverizer. It is also expected that coarse metal, horn silver, etc., which cannot he pnt through a sieve, will pass out of this machine in thin plates.

Tustin's pnlverizer has heen perfected, and ie a good machine. Self-feeding and discharging through sieves, it takes the ore in piecee the size of a walnut, and redncee it to any required finenese. It empties itself completely when the feed is stopped, unless there is coarse metal, or other matter which cannot he pulverized, in the ore. It works wet or dry, and is easily opened for cleaning. This machine is a revolving drnm, in which the ore is crnshed hy means of rollers working on dies. By an ingenione arrangement, it is made to indicate the quantity of ore that it contains at any given time, which is an advantage not possessed hy other machines of the clase. One of these machines has heen at work for a long time in the eampling works in this city, and hae given great satiefaction.

Silver ore ie now heing worked by amelgamation in a series of pans on successively lower levels, the pulp flowing continuonsly through them. The result is ssid to he sstisfsctory, and there is a saving of lahor and expense. The arrsngement ie similsr to that used long sgo for gold, and known as the Hungarian howls. The practice of grinding the pnlp in the psn has heen very generally diecontinued, it having been found that as high a percentage can he got, snd finer hullion, hy crushing the ore finely in the hattery and working the pan with the muller rsised. In thie way, certain hsse ores, eucb ss psrtzite, and ores containing carbonate of lesd, which formerly yielded a low percentage, and hase hullion, when worked raw in psns, sre now treated snccessfully.

On psge 30, it is stated tbst the carbonstes of lime and of lesd canse a large consumption of chemicals in working ore raw. It hss since heen ascertained that, while this ie true ss to acids and as to the protochlorides of copper and iron, it is not so as to the dichloride of copper, which is not decomposed hy such carhonates. Hence, in treating ores containing carhonste of lime or of lead, the dichloride should he prepared in advance, instead of being formed in the pulp.

Dichloride of copper can be made, in addition to the methods described, hy passing sulphurous acid gas into a hot solution of hluestone and salt. A suitable proportion nf salt to use, if the dichloride is to he collected, is rather lese than half the weight of the hluestone. The dichloride is precipitated as a white powder. It dissolves reedily in bot hrine.

Oxide of manganese, sometimes found in conjunction with oxide of iron in silver oree, decomposes hoth of the chlorides of copper, and is therefore an obstacle to their use. Sulphurous acid gas injected to the pulp, will render it harmless. In one csse of this nature it was eaid that good results were ohtained hy pssing a moderate quantity of chlorine gas into the pulp in the nen. This should be done before putting the quicksilver in.

I heve received letters from several gentlemen who were treating ores with hluestone and salt in Purvine psne, and who complained of getting their bullion hase. The Purvine pan is a wooden vessel with a stirrer and copper amalgamating surfaces. I can only account for the base bullion hy supposing that the rapid motion of the pulp in these pans wears away the copper plates.

Prospecting British Columbia.

A party of prospectors have returned to Victoria, B. C., who hsve heen hunting for mines this summer in the interior. After getting well up the Skeena river, in order to get over the larger district of country, esch detachment was supplied with Indinn help. They examined thoroughly all the northeast braoches of thie river, prospecting every stresm coming in from that direction.

The country there ie not a gold-hearing one to any extent. The party then struck over a low divide, not more than 10 miles acroes, to the streams emptying into the Findlay hranch of the Peace river.

This section of the proviace has the appearance of heing much more likely to produce gold in paying quantitiee. Slate and quartz were found in ahundnnce, and small prospects were ohtained in many plscee. Some 25 or 30 streame were visited and named in what is called the Bear Lake region. By the time the party reached those streame, the season was far advanced, and time would not admit of a very thorough examination.

The mountains are hare of vegetation, hnt the valleys are open and greeey, and particularly free from fallen thick timher. In this respect the prospectore were not hindered in the least in their movements. Moose, carihou, hear, grouse and other kinds of game were found in the greatest abnndance, it heing no nncommon thing to have a couple of carihous in camp at the same time. Fieh also were wonderfully plenty. Before going even to the streams emptying into the Findlay, the party penetrated fully 350 miles into the interior of the country.

The proepectors are fully of the opinion that placer diggings will he found on the tribntaries of the Findlay, and that a season epent in that section would develop a mining region that would pay, if not largely, at least good wages. Timher, although not abundant enough to he troubleeome, ie yet to be fonnd in sufficient quantities for all purposes. Grass is in greateet profusion, and covere all the valleye and far up the sidee of the mountaine. In fact, nothing appears to be wanting to supply the wants of a mining population if gold can he found in paying quantitiee; and every member of the party ie of the opinion that thie is only a question of time, and a little more pereevering explorations.

ARIZONA CORRESPONDENT.—Mr. George Madeira, our Arizona correspondent, left this week for Yuma, where he will remain a few days, and will then go into Arizona, visiting Florence, Tombstone, Bisbee and other points in the Territory. Mr. Madeira goes specially in the interests of the MINING AND SCIENTIFIC PRESS, to gather for us informstion concerning the mining and other interests of Arizona. He is also authorized to receive subscriptions, and we hope our friends will favor him where they have an opportunity.

ON the lower levels of the old honanza mines there is now au excellent circulation of air and the men are comfortable at all points where work is in progreee.

California Threshing Machinery.

Our readers at the East and abroad ask us frequently for information, which will give them a better idea of our improved California threshing machinery than they can get from the descriptive articles and advertissements which appear in our columns. They get a knowledge of the special features of the new machinery, but they lack a comprehensive iden of its appearance and the relationship of the parts. This we hope to furnish by the engraving on this page which, though it may lack somewhat in the picturesque is a true portrayal of the machinery as set for operation, for it is made from a photograph taken on the spot.

The illustration represents a complete California threshing rig as now used by our best and most enterprising threshers. The engraving was made from a photograph taken of one of G. W. T. Carter's machines while threshing on the farm of Chas. Sperry, near the Tuolumne river, in Stanislaus county. The rig consists of a Gold Medal separator, Rice strawburner engine, Jackson's self-feeder, elevator and low derrick, water wagon, cook house and "trap" wagon. All except the engine and separator are mounted on Schutler iron-axle wagons.

Although there is considerable machinery used to perform the work, it is handled easily in the hands of an experienced thresher. In less than five minutes from the time the belt is thrown off, everything is on the way to the next stack or setting. Upon arriving at the stack, the derrick is driven close in. The foreman steps off the distance from the derrick for the separator, which is driven in immediately.

The elevator is placed in position, extending from the derrick to the self-feeder. The forkers are setting the guy rope and getting their forks upon the stack. The drivers are getting

A PLANT OF CALIFORNIA THRESHING MACHINERY IN POSITION FOR WORK.

out their ropes, hitch up their horses and begin to fill up the derrick platform.

In the meantime the engineer and fireman have run out the belt from the separator and marked the place for the engine, which is generally driven in so accurately that little shifting is required. As the engine steps, the fireman starts his fire, and as the engine is moved with about 60 or 70 lbs., as soon as the necessary pressure to start up. The belt is run on; the word comes from the foremen, "all aboard," which is responded to by the engineer starting up his engine, and in five minutes from their arrival upon the ground everything is under headway. Twenty minutes is considered ample time to make an ordinary move and get to work.

The grain is taken from the stack with the horse forks and dumped on the platform at the end of the elevator. The "hoe-downs" pull it down with an implement similar to a potato hook; the elevator conveys it to the self-feeder, which carries it to the cylinder. While on its way up the elevator, the grain has to pass under the "spreader," which loosens up all the bunches and perfectly regulates the amount of feed required by the cylinder.

There are employed 3 forkers, 3 drivers, 3 "hoe-downs," 1 sack tender, 1 sack sewer, 1 sack packer or carrier, 2 straw hucks, 1 water buck, foreman, engineer, fireman, trapman and cook—in all, 20 men, and whose wages aggregate $50.75 per day. Fourteen horses are used. The trapman looks after the blankets, traps, etc., goes errands and moves the cook's house, which is shown at the extreme right of the picture. At night the men make up their beds around the stack, and in the morning roll up their bedding and throw it in a pile for the trapman to take care of and have on hand wherever their camp may be at night.

The average work of the machine is about 100 sacks per hour; average weight, 135 lbs. per sack. The last 20 days in the field this season, the rig shown in the picture threshed 20,500 sacks. In the season of 57 days, it threshed 54,000 sacks. The best day's work was 1,404 sacks. This will give an idea of the capacity of this machinery. The amount of steam carried varies from 90 to 100 lbs. The whistle blows at 4:30 A. M. for breakfast; the machine starts at 5, and runs until sundown, with one hour for dinner. The entire outfit cost $4,800 in the field ready for work.

Practical Lectures to Mechanics.

Constructive Processes.

The third in the series of lectures to the mechanics of San Francisco, at Capt. McNevin's Nautical School, corner of Beale and Harrison streets, was delivered on Monday of last week. The subject was "Constructive Processes," and the lecturer Mr. John Richards, superintendent of the San Francisco Tool Works. Mr. Richards spoke as follows:

In 1873 and thereabout, when Prof. Morton, now President of the Stevens Institute, was the editor of the *Journal of the Franklin Institute*, that old and honorable serial drifted into what the boys called "high science." Notwithstanding the efforts of Prof. Morton, who is a most able, and I may add, practical scientific man, the *Journal*, as well as the Institute, became engrossed in dried grasshoppers, petrified toads, the transit of planets, and so on.

The Franklin Institute was founded for the promotion of mechanic art, by mechanics and for mechanics. It was not intended, of course, to confine its labors and aims to constructive processes, but it *was* expected by its founders that applied science should have the first place.

Dissertations on these antiquarian and high scientific subjects are safe and cheap. There is perfect safety in laying down a hypothesis of "prehistoric man," but there is a good deal of risk in venturing an opinion about the cooling

entirely chairman has only allowed me three evenings in which to prepare a paper for to night (two of which were otherwise taken up), and I have concluded to run over some of those old articles, selecting here and there sections that I think suitable, and extemporize remarks when they are required.

Do not, however, imagine that I have wasted four pages of foolscap to explain how shop manipulation came into existence.

The history of the Franklin Institute, which I did not finish, points a strong

Moral for Our Operations Here.

We must, to use a political phrase, deal with living issues—with tangible things. The newest inventions in mechanic art should have the first place. Every week there are new steps made in some branch of engineering and mechanical work. The principal means of progress is by reading, and most of all, the serial publications of this and other countries.

Referring again to the Franklin Institute, I will mention that these crude, unpolished, unscientific articles on practical matters, had the desired effect; not mine so much as others, perhaps. Mr. Cooper's essays on belting, or "bands," which is a much better name, were prominent as a means of awakening interest.

In a few years there was courage mustered up to hold an exhibition of machinery and tools. Thirty thousand dollars of clear profit was made; the Institute was redeemed and once more became what its founders intended, an Institute to promote mechanic art.

Before entering upon the regular lecture for the evening, I want to say a few words respecting

Methods of Studying.

Mechanics have no time to waste in beating the air, and efforts devoted to study should bring the largest possible returns.

Mechanical knowledge reduced to its most simple form, is facts explained by common sense. Reasoning is the great power to be relied upon, and logical deduction the true method. Formulæ, tables, rules, and so on, are only a means of memory; they bear the same relation to mechanical knowledge that a knife and fork does to the food we eat.

Prof. John Swett, of Cornell University, in an address delivered some years ago to the mechanical engineering class of that institution, made this remark:

"When you go out from this place into the world to apply what you have learned here, you will find that it is not what you know that will be paid for; it will be what you can do." This is a great truth, the great fact, indeed, of what is called mechanical education. It is what we *do* that alone has value.

Our Text Books

In time past have been as bad as could be, especially those of an elementary kind. How many of you here can remember the school books, for example, that tell us of the "mechanical powers," the wheel, lever, screw, wedge, and so on. Now, what can a "mechanical power" mean, or be, and if the term can have a meaning, why select a few devices for changing power and motion, and call them mechanical powers? It sounds like the teachings of Aristotle.

Books of reference, containing all kinds of computations, there are no want of; but reasoning books, I will call them, that, explaining why things are so, are not so plenty. The best one I can refer to, and one that will serve as a base for a complete mechanical education is the "Conservation and Correlation of Forces," published about 12 years ago by Harpers, of New York. It does not, I believe, contain a figure, is addressed to the reasoning faculties, and I have never heard of anyone who had read that book, attempt to make a perpetual motion or a contrivance to augment power. I may mention some other books at some future time. This one is enough for the present, and I trust most of you here will procure a copy and read it.

From books we gain general knowledge; from practice we gain special knowledge. Whatever is learned belongs to one or the other of these classes or divisions.

To make this plainer, the laws of forces, the proportion of parts, strength of material, and so on, are subjects of general knowledge that may be acquired from books, and understood without the aid of an acquaintance with the technical conditions of either the mode of constructing or the manner of operating machines; but how to construct proper patterns for castings, or how the parts of machinery should be molded, forged or fitted, is special knowledge, and must have reference to particular cases. The proportions of pulleys, hearings, screws or other regular details of machinery may be learned from general rules and principles, but the hand skill that enters into the manufacture of these articles cannot be learned except by observation and experience. The general design, or the disposition of metal in machine framing, can be to a great extent founded upon rules and constants that have general application; but, as in the case of wheels, the plans of molding such machine frames are not governed by constant rules or performed in a uniform manner. Patterns of different kinds may be employed; molds may be made in various ways, and at a greater and less expense; the metal can be mixed to produce a hard or a soft casting, a strong or a weak one; the conditions under which the metal is poured may govern the soundness or shrinkage—things that are determined by special instead of general conditions.

During the meeting of the British Association in Belfast, 1874, the committee appointed to investigate the means of teaching physical science, reported that "the most serious obstacle discovered was an absence from the minds of the pupils of a firm and clear grasp of the concrete facts forming a base of the reasoning processes they are called upon to study; and that the use of text books should be made subordinate to an attendance upon lectures and demonstrations."

Concrete Facts Concerning Steam Engines

In respect to a steam engine, the concrete facts in part may be named as follows:

To summarize, we have the following propositions relating to steam machinery:

First—The steam engine is an agent for utilizing the power of heat and applying it to useful purposes.

Second—The power of a steam engine is derived by expending water in a confining vessel, and employing the force exerted by pressure thus obtained.

Third—The power developed is as the difference of volume between the feed-water forced into the boiler and the volume of the steam that is drawn from the boiler, or as the amount of heat taken up by the water.

Fourth—The heat that may be utilized is what will pass through the plates of the boiler and be taken up by the water, and is but a small share of what the fuel produces.

Fifth—The boiler is the main part, where power is generated, and the engine is but an agent for transmitting this power to the work performed.

Sixth—The loss of power in a steam engine arises from the heat carried off in the exhaust steam, loss by radiation, and the friction of the moving parts.

Seventh—By condensing the steam before it leaves the engine, so that the steam is returned to the air in the form of water, and of the same volume as when it entered the boiler, there is a gain effected by avoiding atmospheric pressure, varying according to the perfection of the arrangements employed.

If the whole amount of heat represented in the fuel used by a steam engine could be applied, the effect would be, as before stated, from 10 to 15 times as great as it is in actual practice, from which it must be inferred that a steam engine is a very imperfect machine for utilizing heat. This great loss arises from various causes, among which is that the heat cannot be directly nor fully communicated to the water.

(Continued on Page 340.)

THE FRANKLIN GIRDER!

BY FAR THE MOST ECONOMICAL OF ANY CONSTRUCTION MADE.

—o—

This new and economical Girder for Buildings and Bridges, made of any desired length and to sustain any required load, and guaranteed to be fully up to the sustaining capacity represented. The price of these Girders is ABOUT ONE-HALF the price of those of same length and same sustaining capacity in common use in this city. The value of this invention has been most favorably commented on in full by most of the scientific press of this country, as the SCIENTIFIC PRESS, *Scientific American*, *Railway Review*, *The California Architect and Building Review*, *The American Architect and Builder*. A Girder 25 feet long, made for 17-inch wall, with about 2 feet of brick wall on it, is now in front of premises 231 First St., above Shot Tower. This Girder held on the top of the brick wall now on it, 117 Tons and 1,741 Pounds of Railroad Iron, at the Pacific Rolling Mills, piled directly over and between supports, and it would have held, in the opinion of experts 200 tons, as the deflection was not a quarter of an inch below the true arc. The foundation on which the Girder rested, settled 7 inches, so that the loading had to be stopped at the above weight.

The Price of these Girders, 25 feet Long, to Sustain 100 Tons as a Safe Distributed Load, $200.

THOSE IN COMMON USE NOW IN USE IN THIS CITY COST NOT LESS THAN $400.

And other sizes in like proportion. Every Girder guaranteed to sustain the load as a safe one; the breaking load being three times greater.

Prices for any Size and Sustaining Capacity given on Application.

PATENT RIGHTS FOR STATES FOR SALE.

Portable Mulay Saw Mill,

With improvements recently made is unequaled as a neighborhood mill. It can be run by either steam or water power, and is especially adapted to the engines used for threshing.

It may be operated by either two or three men, and will cut as much lumber in proportion to the power and number of hands employed as mills of larger capacity.

It makes smooth and even lumber, leaves no stubshot, and will cut any sized log up to four feet in diameter. It may be transported from one locality to another and re-erected ready for sawing in from two to three days, and can be made profitable in localities where there is not sufficient timber to justify the erection of a large mill. Send for descriptive circular, price, etc., to CHANDLER & TAYLOR, Indianapolis, Indiana.

We also build the heavy Standard Circular Saw Mill, with either one or two saws as well as the Pony Circular Saw Mill that is capable of being run with light power. We also build Stationary Engines of varied capacity; also, portable Threshing Engines.

DEWEY & CO.'S
Scientific Press  Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYOERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

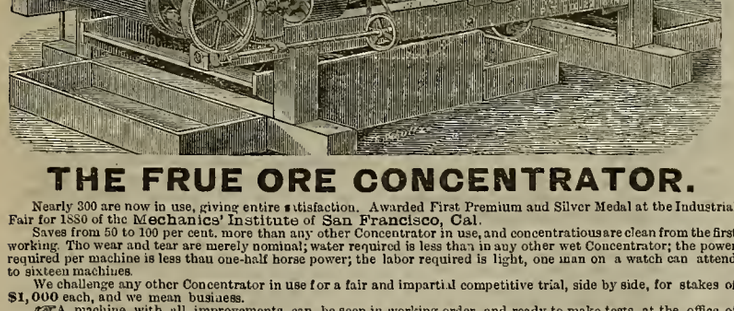
Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO.,
SAN FRANCISCO, CAL.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

ENGINE LATHES IN SECTIONS.

Limit of weight for 25-inch Lathes, 300 pounds. For 17-inch Lathes, 150 pounds.

NOW READY,

Planing and Shaping Machines 50x20 inches.
1 25-inch Engine Lathe to turn 12 feet long.
1 Eastern 15-inch Engine Lathe to turn 30 inches long.
2 15-inch Engine Lathes, Single Gear, Screw Cutting.

SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

THE O'HARRA CHLORIDIZING FURNACE.

Patented in 1878.

SIDE ELEVATION OF THE O'HARRA FURNACE.

This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

A cheap Furnace to build and to run.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.

At Washoe and Ophir Tailings Mill it costs $1 10 per ton to work 40 tons in 24 hours.

At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.

Lewis Chalmers, of the Isabella O. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenual sulphurate of silver up to from 84% to 95% of the assay.

SEND FOR DESCRIPTIVE CIRCULAR TO

WHITNEY, VEASEY & CO.,

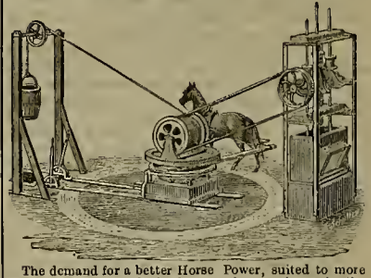
New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.

This power is light and strong, so that two or more horses can be used for crushing ore or other work.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CHIMNEYS.—L. E. Clawson, S. F. Dated, Nov. 8, 1881. No. 249,308. This invention relates to certain improvements in chimneys of that class in which an interior flue is employed for the purpose of conducting away the smoke and gases, and an exterior casing may surround the interior flue, either with or without a filling between the two of plaster of paris or fire clay, for the purpose of safety. It consists in building a chimney in sections of earthenware tube, which are supported upon a suitable base provided with a slide, through which any accumulations may be removed from time to time, and in combination with such a sectional chimney a series of flanges so constructed as to unite the sections and at the same time provide independent supports for the chimney at intervals.

HORSE POWER.—Chas. H. Baker, S. F. Dated, Nov. 1, 1881. No. 248,906. This invention consists in a horizontal drum revolved by a vertical gear wheel, engaging with gear crown-plate, the latter being operated by an extended lever or tongue, which is connected with or disconnected from said crown-plate by means of certain devices operated by a lever. It also consists in certain details of construction, together with a braking mechanism, by which the drum may be prevented from slipping back or stopped when necessary. The object is to provide a horse power for lifting purposes, or for driving machinery, or for both combined, as when used to hoist ore from a mine, and at the same time operate a stamp mill.

THE LABORING MINERS.—The "laboring miners" are but poorly understood by many people in the State. Certain papers have spread the belief that these miners are a sort of half civilized, wicked and ignorant set of men, who neither know nor respect the law. Now, we have no doubt that the miners, as a class, know much more about the legal points now involved and yet to arise in the elickens contest than do the average business men of Marysville or Sacramento, who are equally interested in the result. Furthermore, these miners do not for a moment demand that any other industry shall be sacrificed that they may continue to exist. They know that there are measures within reach by the adoption of which they will be enabled to continue their own labors without further injury to their neighbors in the valleys. They are determined that these measures shall be carried into effect. It is no matter of guess work with them. If they cannot bring the grangers to a reasonable way of thinking in one way, they must do it in another. They make no statements, neither do they commit any acts that are not "justified by the situation," for they are too well posted to do that. Their ideas of what is justifiable in this connection may not accord with the views of the granger lawyers and press, but that makes no difference. Like Davy Crockett, they know they're right, and they propose to go ahead as they have begun.—*Nevada Transcript.*

THE first piece of gold found in California weighed 50 cents and the second $5. Since that time one nugget worth $43,000. two $21,000, one $10,000, two $8,000, one $6,500, four $5,000, 12 worth from $2,000 to $4,000, and 18 from $1,000 to $2,000 have been found and recorded in the history of the State. In addition to the above, numberless nuggets worth from $100 to $500 are mentioned in the annals of California gold mining during the last 30 years.

THE country surrounding San Andreas for several miles in extent contains very valuable mineral land; placer grounds have been merely gophered out here and there in wet winters, and will probably remain idle for some time until sufficient water is brought for working purposes. Quite a number of quartz mines in the vicinity are being worked in a profitable manner.

Practical Lectures to Mechanics.

(CONTINUED FROM PAGE 337.)

To store up and retain the water after it is expanded into steam, a strong vessel, called a boiler, is required, and all the heat that is imparted to the water has to pass through the plates of this boiler, which stand as a wall between the heat and its work.

Now, what I will ask, would be the use of studying proportions, the laws of expansion, combustion, and so on, until these concrete facts had been learned?

In Respect to Water Wheels,

Which rank second among motive agents, the same remark holds good. I fear you will think I am making war on text hooks, but I am not—only trying to show their scope or place—their subordinance to concrete facts. You all know the classification of water wheels in common rudimentary text hooks. The overshot, undershot and breast wheel; with perhaps some mention of the turbine and reaction wheels. Such classification does not lead to correct conclusions; does not, in this language of the report quoted, form a basis for the reasoning processes. Water wheels should be classed as follows:

First—Gravity wheels, acting directly from the weight of the water which is loaded upon a wheel revolving in a vertical plane, the weight resting upon the descending side until the water has reached the lowest point, where it is discharged.

Second—Impact wheels, driven by the force of spouting water that expends its percussive force or momentum against the vanes tangental to the course of rotation, and at a right angle to the face of the vanes or floats.

Third—Reaction wheels, that are "enclosed," as it is termed, and filled with water, which is allowed to escape under pressure through tangental orifices, the propelling force being derived from the unbalanced pressure within the wheel, or from the reaction due to the weight and force of the water thrown off from the periphery.

Fourth—Pressure wheels, acting in every respect upon the principle of a rotary steam engine, except in the differences that arise from operating with an elastic and a non-elastic fluid; the pressure of water reeting continually against the vanes and "abutment," without means of escape except by the rotation of the wheel.

Going a little farther with this matter and referring to turbine wheels, these are the subject of the most abtruse computations. These computations are essential; they furnish proportions, curves, capacity and so on, but below all this lies the concrete facts again. To illustrate I will name the main ones:

First—The spouting force of water is theoretically equal to ite gravity.

Second—The percussive force of spouting water can be fully utilized if its motion ie altogether arrested by the vanes of a wheel.

Third.—The force of the water is greatest by its striking against planes at right angles to its course.

Fourth—Any force resulting from water rebounding from the vanes parallel to their face, or at any angle not reverse to the motion of the wheel, is lost.

Fifth—This rebounding action becomes less as the column of water projected upon the wheel are increased in number and diminished in size.

Sixth—To meet the conditions of rotation in the wheel, and to facilitate the escape of the water without dragging, after it has expended its force upon the vanes, the reverend curves of the turbine is the best known arrangement.

This matter of concrete facts ie eo important that I do not like to leave it, even if thie evening's lecture does not reach turning, drilling, planing, forging and so on.

Power, or force and motion, ie a

Product of Heat.

That seeme a strange fact, but it is true in the fullest sense.

All motive machinery euch as steam engines, gas engines, air enginee, water wheele and wind wheels, are simply agente for utilizing or transforming heat into work. This you will find fully explained in the book before referred to.

This "concrete fact" which I want to call your attention to is, that all these agents or mechanics act upon the same general principle, that of expansion.

Force and Expansion.

The pressure or power of a steam boiler is due to expansion; that is obvious. In water power we utilize the gravity of the water as it passes from a higher to a lower level, but if we consider how the water reached this higher level, it will be found a result of expaneion. The heat of the sun's rays converts water to mist, expands it in fact, until it is lighter than air when it ascends, becomes condensed again and descende as rain, turning water wheels in its course to lower levels. In respect to wind power, the expansion of air hy heat is the main, or, indeed, the sole cause of wind currents, as it is of water currents. The sun, then, becomes the prime mover, so to speak, manifesting itself in curious but regular sequence. The heat employed for expanding water in steam boilers is from coal, and this coal, to use a remark of Prof. Rankin, is condensed rays of the sun—ie heat given out thousands, or, perhaps, millions, of years ago, and stored up in the earth for our present use.

[The remainder of Mr. Richards' lecture, which we shall give next week, is on machinery of application, in which he describes at some length the operations of forging, steam hammers, combined machines, etc.—EDS. PRESS.]

Thanksgiving Day.

The Governor's Proclamation.

STATE OF CALIFORNIA,
EXECUTIVE DEPARTMENT.

In accordance with the proclamation of the President of the United States, and in accord with the time-honored custom, now grown into a national observance, I, George C. Perkins, Governor of California, by the authority in me vested, do proclaim Thursday, the 24th day of November, as a day of thanksgiving, and request that it be set apart as a day of prayer to Almighty God in acknowledgment for the manifold blessings he has bestowed upon us as a nation. Following the example of our ancestors, let it also be a day for interchange of friendly greetings, family reunions and social recreations.

The past year has been overshadowed by a great national sorrow. The hand of the assassin has deprived us of our Chief Executive, our hearts have been overcharged with grief, mourning has draped our land in gloom, the nations of the earth, living under governments adverse to the principles which are the strength and support of our beloved land, have paid a tribute to the departed President unequaled in the annals of history. Peacefully has his chair been filled. No commotion, no violence, no discontent marks the change. The permanency and stability of our political institutions are established beyond a doubt, and the nation has proven itself composed of a conservative law-abiding people. While partaking of home pleasures and participating in family enjoyments, forget not those who are denied the privilege of both home and family. Extend the helping hand; yield to the stranger and wanderer the sympathy of your hearts; let kindness, and mercy and good-will to one another be the marked characteristics of Thanksgiving Day.

I would especially invoke the aid of the people of this State in behalf of the Veteran's Home Association of California—this day having been set apart by the Executive Committee of said association for such free-will offerings as our people may deem proper to donate. To the extent of your ability contribute to this worthy cause. Remember that the blessings which are ours this day came through them periling life and limb to keep this nation one and indivisible. It is not charity they ask, but justice. We owe it to them—it is an obligation, the fulfilment of which has been already too long delayed. I know this appeal will not be in vain—for the liberality and patriotism of Californians are never lacking when it is demonstrated that the exercise of those virtues are necessary for the aiding of a worthy and noble purpose.

In testimony whereof, I have hereunto set my hand and caused the Great Seal of the State to be affixed at Sacramento, California, this fourteenth day of November, A. D. eighteen hundred and eighty-one.

God save the commonwealth.

[SEAL.] GEORGE C. PERKINS, Governor.

By the Governor:
D. M. BURNS, Secretary of State.

Brief Mining Notes.

COLORADO'S bullion output this year will probably be about $23,000,000.

IT IS proposed to work ore worth $5 per ton, at a profit, in the Black Hills.

AIR pipes have been extended to the lower levels of the Con. Imperial, and work is about to be fully resumed at all points.

FOUR or five companies in Como are still diligently pegging away at their mines. The perseverance of the Comoites deserves to be well rewarded.

O. W. EASTON, a "49er," and well known in mining circles, died last week. He was lately directing mining operations on the Mariposa estate.

THEY have put a hydraulic gravel elevator at work in the river bed of the Middle fork of the American river near Hoosier bar, and it is said to be doing good work.

THERE is said to be a mountain of copper ore in the White Cloud mines, near Lovelock, Nev., and it is situated in the heaviest belt of nut-pine timber in the State.

THE proprietors of the smelting works, near Shell Mound park, have found it necessary, on account of the recent rush of business, to build a large addition to their works.

UPWARDS of $1,000,000 in gold was received by the last Australian steamer, all of which was in sovereigns, except about $125,000 This gold has all gone to the San Francisco Mint.

AS an indication of the change in the center of mining business, during the last six months $2,602,750 were paid in dividends in San Francisco, and $2,461,500 in New York and Boston.

A LARGE number of white men will go to the Yakitat country, Alaska, in the early spring to prospect. All the indications are that valuable discoveries will be made. Gold placers are looked for.

BESIDES doing a good deal of prospecting here at home, residents of Comstocke are sinking shafts, running tunnels and otherwise prospecting about a dozen gravel mines in various parts of California.

THE numerous friends of Judge C. C. Goodwin, formerly of the Virginia *Enterprise*, now editor of the Salt Lake *Tribune*, will be pleased to learn that he has become wealthy through a lucky mining investment.

AT Butte, Mon., there are four smelters in operation, and another in course of construction. There are six roasting mills running, and a large one building. The Alice and Moulton are the big mines of the camp.

IN alluding to the fact that the new gold mines of New York are found near Saratoga, the Grass Valley *Tidings* says it seems a wise provision in nature when it is considered how people who visit there are charged.

News in Brief.

BODIE has not over 3,000 inhabitants at present.

IT IS reported on good authority that the relations between Mexico and Guatemala are very critical.

DURING the last fiscal year there were 10,871,943 acres of Montana land sold and granted to railroads.

TWO passenger coaches of the Colorado Central train were Saturday blown from the track, near Colorado.

THE United States steamer *Alliance* has arrived at New York after five months' fruitless search for the *Jeannette*.

THE narrow gauge railroad from Bodie to Mono lake is completed. It is 30 miles in length.

GOULD'S Southwestern system will within a few days have connection with the Southern Pacific by the New Orleans branch through Shreveport, La.

DIPHTHERIA, scarlet fever and small-pox are devastating the center and south of Russia. The severity of the diseases exceeds anything heretofore known.

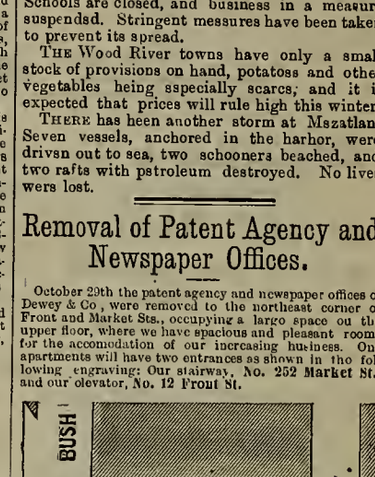
SMALLPOX still rages in Dayton, W. T. Schools are closed, and business in a measure suspended. Stringent measures have been taken to prevent its spread.

THE Wood River towns have only a small stock of provisions on hand, potatoes and other vegetables being especially scarce, and it is expected that prices will rule high this winter.

THERE has been another storm at Mazatlan. Seven vessels, anchored in the harbor, were driven out to sea, two schooners beached, and two rafts with petroleum destroyed. No lives were lost.

Removal of Patent Agency and Newspaper Offices.

On October 29th the patent agency and newspaper offices of Dewey & Co, were removed to the northeast corner of Front and Market Sts., occupying a large space on the upper floor, where we have spacious and pleasant rooms for the accomodation of our increasing business. Our apartments will have two entrances as shown in the following engraving: Our stairway, No. 252 Market St., and our elevator, No. 12 Front St.



☞ Take the Elevator at No. 12 Front St.

Visitors will find it better to step around the corner from Market St., to the elevator rather than ascend the stairs. Old and new friends are cordially invited to give us an early call in our new quarters.

The Mining and Scientific Press

Established May, 1860, this has long been the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, $4 a year in advance. Sample copies, 10 cts.

DEWEY & CO., PUBLISHERS,
No. 202 Sansome St., cor. of Pine, S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

O. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.
E. W. CROWELL—Yuba and Sutter counties.
D. W. KELLEHER—San Mateo and Santa Clara counties.
C. E. WETMORE—Alameda county.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

BOOKSELLERS, STATIONERS, ETC.—Messrs. Peyot, Upham & Co., No. 204 Sansome Street, are one of the oldest, most enterprising and reliable firms in the book and stationery trade in San Francisco. Scientific, industrial and foreign publications are a specialty with them. They are also noted for their first quality of blank book and fine stationery line of goods.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

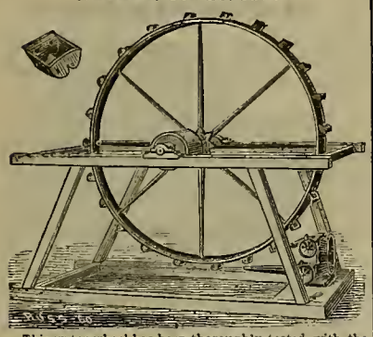
THE PELTON

WATER WHEEL.

(Patented, Oct. 26, 1880.)



This water wheel has been thoroughly tested with the Dynamometer, and utilizes 78% of the theoretical pow r; and underheads of water of 75 to 800 ft ie guaranteed to give better satisfaction than any Turbino or other wheel ever offered to the public. The above per cent, is due to the peculiar shape of the buckets used. They do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized, without any part of the water coming in contact with the bucket following. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used. These buckets can be taken off in transportation, and can be replaced by new ones when worn out by sand in the water; also can be applied to wooden wheels when desired.

DIVIDEND NOTICE.

OFFICE OF THE

Silver King Mining Company,

SAN FRANCISCO, NOVEMSER 8, 1881.

At a meeting of the Board of Directors of the above named Company, held this day, a dividend (No. 23) of Twenty-five Cents (25c) per share was declared, payable on TUESDAY, November 15th, 1881, at the office of the Company, Room 10, No. 328 Montgomery street, San Francisco, California. Transfer books will be closed on November 9th, 1881, at 3 P. M.

JOSEPH NASH, Sec'y.

Newcastle Gold Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Yankee Hill Mining District, Placer County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Twenty-third (23) day of September, 1881, an assessment, (No. 2) of two (2) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 33, No. 318 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the First (1) day of November, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Twenty-first (21) day of November, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale,

E. G. MATHEWS, Sec'y,

Office—Room 33, No. 318 Pine St. San Francisco, Cal.

POSTPONEMENT. — The day of delinquency of the above assessment is hereby postponed to the fifteenth day (15) of November, 1881, and the day of sale to Monday the fifth day (5) of December, 1881. By order of the Board of Directors, November 2, 1881.

E. G. MATHEWS, Sec'y.

Newcastle Gold Mining Company.—Location of principal place of business, San Francisco, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 27) levied on the twenty-third day (23) of September, 1881, the several amounts set opposite the names of the respective stockholders as follows:

Names.	No. of Cert.	No. Shares	Amt
O. C. Marsh, Trustee	41	1000	$ 20 00
C. C. Marsh, Trustee	42	4000	80 00
C. O. Marsh, Trustee	44	300	6 00
A. B. Grogan, Trustee	45	12500 bal.	210 00
G. P. Thurston, Trustee	46	12500 bal.	230 00
G. P. Thurston, Trustee	48	10000	200 00
G. P. Thurston, Trustee	49	10000	200 00
G. P. Thurston, Trustee	50	5000	100 00
G. P. Thurston, Trustee	52	3500	70 00

And in accordance with law, and on an order of the Board of Directors, made on the second day (2) of November, 1881, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, Room 33, No. 318 Pine Street, San Francisco, California, on Monday, the fifth day (5) of December, 1881, at the hour of four o'clock P. M., of said day, to pay said delinquent assessment thereon, together with the cost of advertising and expenses of sale.

E. G. MATHEWS, Sec'y.

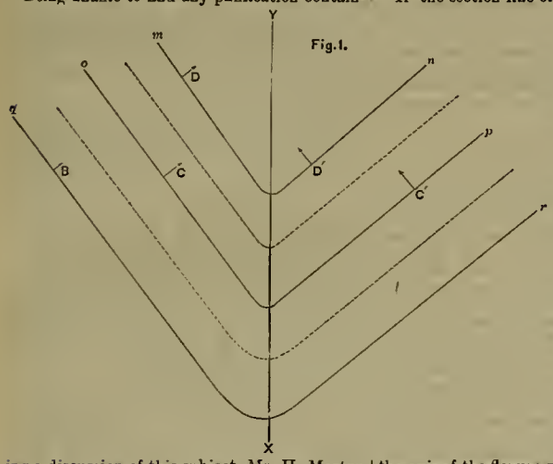
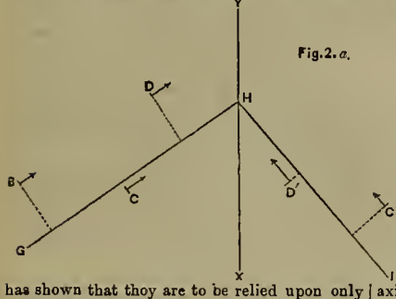
Construction of Geological Cross Sections.

In some of our technical schools and colleges the student is required to construct or copy a number of profile sections of his routine work; but little attention is given to the methods of projecting observed dips and exposures upon the section line, and still less to the method of constructing the under (or above) ground curves. As a result of this instruction every engineer or geologist is compelled to invent for himself a system, or copy the style of others.

Being unable to find any publication containing a discussion of this subject, Mr. H. Martyn Chance, Assistant Geologist of the Pennsylvania from data obtained at the surface, but the experience of engineers in the anthracite coal fields has shown that they are to be relied upon only in exceptional instances.





The possibility of indicating underground survey, prepared a paper on the subject of "The Construction of Geological Cross Sections," which was read before the American Institute of Mining Engineers, as follows:

Geological profile sections have frequently been used to determine underground structure curvatures from dip angles observed at the surface has been found to be limited to a mere approximation of the larger flexures. As a means of predicting the depth and shape of minor rolls, they have been found most unsatisfactory. In the anthracite coal fields, the hypothecated structure in undeveloped ground is usually introduced upon the working profiles in pencil lines only, and as development progresses, frequent changes are necessitated by the eccentricities of individual seams.

I wish to invite attention to the methods commonly used in the construction of cross sections, and to indicate some of the reasons why these must always fail to give trustworthy results.

We may consider these points under three heads:

1. The location of the section line.
2. The projection of dips and exposures.
3. The construction of underground curves.

Having given a series of exposures and dip angles located geographically upon a map, the best position for a section is generally conceded to be along a line drawn midway between these exposures and at right angles to the line of strike, *i. e.*, parallel to the direction of the dip.

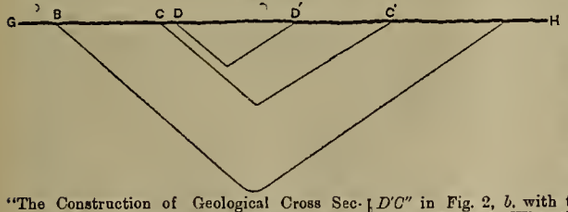
If the section line cross is an anticlinal or synclinal axis decidedly inclined to the horizon—that is, when the opposing dips are not parallel and the lines of strike on opposite sides of the axis converge—the section may often be best located along a broken line, the lengths of which are drawn at right angles to the local strike; or it may be constructed on a line drawn at right angles to the axis, when this bisects the flexure; or on a line drawn at right angles to a line bisecting the angle formed by the converging strike lines.

Thus in Fig. 1, three coal beds, *B*, *C*, *D*, are exposed at the points, *B*, *C*, *D*, and *D'C'*, dipping as indicated by the arrows; the line *XY* is the axis of the flexure, rapidly declining towards *Y*. The lines *mn*, *op*, *qr*, are water-level contours, drawn through the different seams, representing, therefore, their "line of strike." The dotted lines are introduced to show the method of locating hypothecated horizons.

The best methods of constructing a section through these exposures is illustrated by *Fig.* 2, *a* and *b*, in which the section line, *GHI*, is a broken line, the segments of which, drawn parallel to the opposing dip-angles, intersect on *XY*.

The resulting section shows the absolute thickness of the strata between *B* and *C*, and between *C* and *D*, and the agreement between the thickness *DC''* with that determined at *D'C''* furnishes a good check on the accuracy of the construction.

Two very objectionable methods are shown by Fig. 3, *a*, *b* and *c*. The section line GH is drawn at right angles to the axis, XY, and midway between the located exposures. The first section, Fig. 3, *b*, is obtained by projecting the dip-angles upon the section line, *in prolongation of the line of strike*. This is the only proper way of projecting exposures, and will always give a section mathematically correct for the adopted alignment, but the thickness of measures as represented by the section is much greater than the true thickness. This can be seen by comparing *D'C''* in Fig. 2, *b*, with the same line in the section, Fig. 3, *b*. When this method is adopted, a prominent "N. B." should always direct attention to this exaggeration.



The section, Fig. 3, *c*, shows the absurd construction that results if the dip-angles are projected at right angles to the section line.

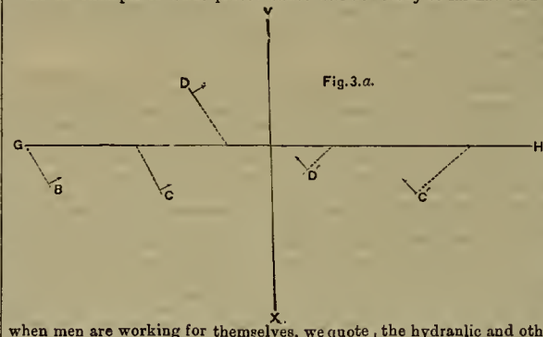
Difficulties in the identification of coal seams on opposite sides of a basin may frequently arise from distortions of this kind.

THREE more of Capt. Williams' Alaska exploring party returned the other day from that region. The *Turner* picked them up at St. Michaels, some ten days before the *Corwin* rescued the four members of the party who returned on the cutter some weeks since.

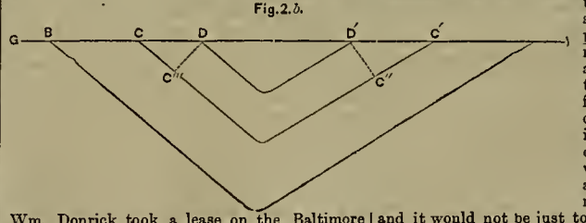
Working Mines on Lease.

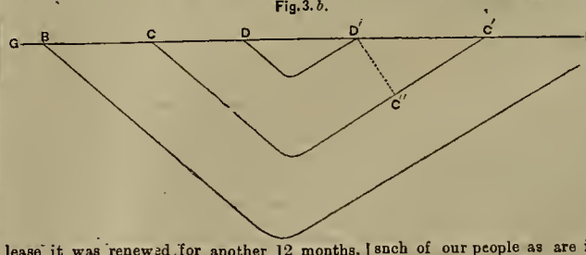
Leasing of mines by practical miners from the owners has, until lately, been a thing almost unknown on this coast; but now whole mines, or portions of them, are leased to gangs or companies of working miners, who make more or less, according to the ore. When work of this kind is properly superintended, it is often a good thing for both parties, for the mine is properly opened and developed for the miners, while the miners, working for themselves, put in their best licks.

As an example of what perseverance will do when men are working for themselves, we quote an item from the Georgetown *Courier* of Colorado, which, referring to the Baltimore tunnel, says:



Two years ago John Pomeroy, John Foote, Wm. Foote, Thos. Foote, Thos. Bonds and Wm. Donrick took a lease on the Baltimore tunnel for one year, having the ground from the tunnel level to the surface. They commenced drifting without ore, and had none for the first 100 ft, but since that time the ore has been continuous. On the termination of the lease it was renewed for another 12 months, which will expire with the present month. During the two years they have made from $200 to $225 per month to each man. The highest amount reached in any one month was $640 to the man. The output has been remarkable for its regularity. They have run the drift between 300 and 400 ft., and stoped it mostly to the surface.





A contract was let last week to drive the tunnel 200 ft. at $22 a ft. It is now in between 600 and 700 ft.

CAPITALISTS must learn that they must go underground several hundred feet to work to good advantage. A correspondent sensibly says: A company of men who are so close and near-sighted as to pay $100,000 for a mine, and then refuse to go down any further than they can reach with a 200-ft. windlass rope ought to lose the mine and all they put into it.

The Gold Run Suit.

The case of the People vs. The Gold Run Ditch and Mining Co. is on trial at Sacramento. The case is watched with interest all over the State. As judging from the character of the evidence, it is evidently intended to go over the whole question of the debris. From the evidence already presented by the prosecution, it would appear as if weeks of time are to be consumed in the hearing of testimony, and the whole history relating to the mining deposits in the American river fully investigated. The testimony so far has been for the purpose of showing the depth of the deposit in and about the month of the American, and to prove overflow and damage to the town of Washington and adjacent country as this consequence.

The Grass Valley *Union* of the 20th says in this connection: The prosecution doubtless has an object in having the testimony so elaborate on this point, but the defence will be willing to concede that the filling of the American river is due largely to the hydraulic and other mining carried on upon the main river and its tributaries. They can properly deny, however, that they are responsible for that deposit or any damage resulting from it. The Gold Run Co. may have contributed something to this river deposit, but that is hardly susceptible of the proof that is necessary to obtain a permanent injunction. The debris from the Gold Run claim that escapes into the tributaries of the American would make scarcely a showing at the month of the river, and it would not be just to make the company responsible for what is the combined result of the twenty years mining of all kinds in a large part of the two counties of Placer and El Dorado. The prosecution is going over a wide field to make its point against the Gold Run Company, but so far it is not evident that they have shown any ground for the permanent injunction demanded.

COPPER IN THE EAST.—Judging from the following paragraph from the Boston *Economist*, such of our people as are interested in copper mines need not fear to go ahead and develop their properties, as there appears to be no danger of causing copper to become a drug in the market: "The copper mining interest continues to grow in importance, and the prices of ingots are well maintained. Lake Superior loses none of its importance in the market consequent upon developments in other sections, and we look forward to increased demand at steady prices. Sales at 18 afford a profit, and stimulate the working of increased forces in all copper districts."

THE Calaveras *Chronicle*, a journal which is so well managed as to pay more than ordinary attention to local affairs, and one in which we always find something worthy of reproduction, has entered on its 31st volume.

CAYUGAS is the principal headquarters town, of Safford district, Nev.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Ede

The Revolution.

EDITORS PRESS:—We have had already many revolutions in metallurgy—on paper; hut now comes something more serious, accnrding to an article in the New York *Times* of Octoher 12th. It is the Hamilton lead amalgamation procees, to which you have referred in the PRESS. The *Times* eays that the obstinacy of the tailings from the quicksilver amalgamation, to retain 40% of the silver aud gold of the ore, is now completely overcome.

For the Hamilton process, tbe ore is first pulverized, then roasted; after this amalgamated with lead in a red hot state, and finally the lead, saturated with silver and gold, treated either hy the zinc process or hy crystallization. All this ie performed with the cost of $1 per ton, or even less. So it is printed hlack on white. Works are already in erection in New York capahle of treating 100 tons per day, having one "magnificent" rotary desulphurizing cylinder furnace—7 ft. in diameter and 52 ft. long—fed automatically, "with far more regularity than if fed hy hand." There are four connecting dust chambere, catching any of the ore that might escape up through the stack hy the strong hlast. The furnace is lined with fire bricks, with projecting shelves on the inside. It is also halanced nicely; "one man can easily rotate it hy hand." That of course means when empty; a volume of gas heing injected hy a Root's hlower, which eliminates the gaseous, ohnoxious vapors, and is carried out through the chimney stack into the outer air.

From the roasting furnace tbe ore is conveyed into a vacuum furnace and passed through a hath of molten lead. This piece of machinery is a marvel of wonder. The ore hy euction ie taken through 30 tons of molten lead, wherehy each and every particle of precious metal comes in contact automatically with the said molten lead. The lead in running into the pipe creates a suction that conveys the ore with it, and, dropping through the cast iron pipe, mingles freely with the gold and silver. The lead and ore rise in the pot, hut that the extraction may he complete, and "the alloy not permitted to adhere to the gold and silver," a numher of riffled plates are attached to the stand pipe of the pot. The lead is kept in continual circulation until it is fully charged with the precious metal, absorhing one-fifth of its weight in gold and silver.

"Hundreds of carloads of ore are from all parts of the country on the way awaiting the etarting of the works. A prominent Comstock operator offsred $100,000 for the right of one county alone in Nevada, the offer heing promptly and ahsolutely refused." Serves him rigbt. Why did he not offer two millions! The shares are sold now at premium.

To convince non-helievers, the *Times* gives the followiug parallsl to show the similarity and difference between amalgamation by quicksilver and lead.

QUICKSILVER OR CHEMICAL AMALGAMATION.	LEAD OR METALLURGICAL AMALGAMATION.
"1. The ore is reduced to a pulp with a mixture with water."	"1. The ore is ground fine in a dry state."
I should like to know where the ore is ground wet for roasting.	
"2. The ore is submitted to chemical treatment in the cold."	"2. The ore is roasted at high temperature."
So far as I know, the ore is roasted at a proper temperature for quicksilver amalgamation.	
"3. The mercury is mixed thoroughly with the ore previously chemically treated."	"3. The pulverized ore previously heated is thoroughly mixed with the molten lead."
"4. The mixing is done mechanically."	"4. The mixing is done automatically."
There is a similarity here.	
"5. Amalgamation takes place in the cold."	"5. Amalgamation takes place at red heat."
Nobody amalgamates here cold.	
"6. Mercury is a metal fluid at ordinary temperature, and is an expensive metal."	"6. Lead is a metal, solid at ordinary temperature, and one of the cheapest metals."
Mercury is fluid, lead is solid; that is true	
"7. Amalgamation by quicksilver is a long process and tedious, and always in complete operation. Meanwhile much of the precious metals, as well as the mercury is lost, both chemically and mechanically."	"7. Amalgamation by lead is instantaneous. Very little lead is lost chemically; none mechanically. Much lead is gained in treating some ores and none of the gold or silver can escape, no matter how fine or light the particles may be."

No. 7 is written for greenhorns exclusively. The question is not whether the amalgamation is instantaneous or not, hut how long will it take to get the silver bullion in hand. Roasting takes the same time in hoth cases. The amalgamation with quicksilver takes six hours, retorting again, six; melting, two hours, and the bar is ready. This is good for 3 tons or 100, according to the number and size of pans. The amalgamation with lead naturally must he conducted in a large amount of lead, and the separation of 30 tons of lead from precious metals hy zinc or cupelation is a "long and tedious operation," and the har will not be in hand before 48 houre, if at all. How 100 tons of ore can pass through a hath of lead without causing a mechanical lose is certainly a "marvelous wonder," as well as that no particle of gold or silver can escape. A proper roasting and amalgamation in pans is turning out the silver and gold within 90% generally, often 96%; and if the Hamilton process can do the same at a cost of $1 or 75 cents per ton, then it will he time for our foundries to hurn up their patterns nf amalgamating machinery, hut there is no danger in that direction. K.

San Francieco, Nov. 17, 1881.

Silver Canyon.

A week or so ago we made a hasty trip to this promising little camp. It is situated nn the east elope of the Schell Creek range, pretty well up in the mountain. As yet thcre is hut little business outeide of that carried on hy Dr. Brooks' company. Through the courtesy of foreman Mickel, we were then taken through the principal mines of the company and shown the work that is heing prosecuted under his management. At the Sadie L. a great deal of work hae heen done and considerable high-grade ore taken out. All the indications in this mine point to yet undeveloped ore hodies of great value at greater depth. The Blue Bslle, several hundred ft. higher up, aleo looks well, and has some very rich ore in sight. Infact, a large scope of ground in that section, most of which is tho property of the company, gives unmistekable proofs of heing richly mineralized. All that is nesded is time and lahor to hring out the latsnt resources of the dietrict. The compauy give employment to hetween 40 and 50 men at the mines and mill. The mill ie of 10 stamps cepacity, almost new, and gives perfect satisfactiou. There ie an ahundance of pine timher adjacent to the mines and mill to supply the camp for years to coms. The canyon is possessed of all the resources to hring out one of the hest mining districts in this section.

There is one store, kept hy Gerraghan & Poujade, one saloon hy Jas. McNulty, and Mr. and Mre. Sommerlott conduct the two boarding-houses at the mines and mill. J L. Roherts o), an old-time pioneer of Treasure Hill, runs the motive power at the mill as well as Uncle Sam's postal affairs. A small log schoolhouee, sufficient for present demands has heen built.—*White Pine News.*

"FLOAT" MINERS.—Down in Mud Springe township (and perhaps in other parte of the county), there are men and boys, quite a number of them, who make a comfortahle euhsistences, and occasionally quite a "strike," in exploriug ravines, croppings and old piles of tailings for "float" (detached chunks of quartz) of promising appearance, wbich they pile up in little heaps at convenient points until a few tons are gathered together, when they hire a teamster to haul it to some neighboring quartz mill, where an agreed price per ton is paid for crushing it. Col. Staples, at the Pocohontas mill, does this description of crushing at $6 per ton. The price for hauling ranges from 75 cents to $2 per ton. In some instances "float" hunters, after paying for hauling and crushing, have heen known to realize from $8 to $12 for their lahor, hut it is generally practiced hy hoys who are satisfied if, for the odd hours throughout the summer which are thus employed, they realizs enough to "keep even" on hilliards, cigars, etc., through the winter. In some cases, however, of experts in quartz and its manipulatiou, fair wages are made in selecting "float," pounding it up in a hand mortar, and panning it out. One gentlemen of good standing and repute, a rancher of Mud Springs township, assured us that during one winter he had made upwards of $700 in this manner, working at this business only on euch days as could not he profitably employed in connection with his business of farming. He ehowed us a pile of "float," estimated to contain hetween three and four tons, from which he expec'e to take out not less than $150 during the rainy days of next winter.—*Mountain Democrat.*

A NEW MINING DITCH.—The Yreka Creek Mining company are hurrying along the work of getting ready for winter. A hulkhead, or wing-dam, some 1,400 ft. long, is being constructed. The new elevator lately received is also heing placed in position, and the other one is to be moved as soon as the new one is ready for work to keep the pit clear of water. In addition to this work, arrangements are heing made for the construction of a ditch immediately to carry the water of Forest House creek to the reservoir, and also to enlarge the ditch ahove the reservoir to Guy's gulch and Cram's gulch, also to enlarge the ditch from the reservoir to Hawkinsville, so as to furnieh 1,360 inches of water, which will keep two elevators in operation during the next four months. By the end of this time the upper ditch will he enlarged all the way to Shasta river, to keep up the supply when the watei is scarce in tbe creeks and gulches nearest the reservoir.—*Yreka Journal.*

THE turning in of a sufficient amount of cold water to work the hydraulic pump should, to a noticeahle extent, the *Enterprise* thinks, cool the water in the Sutro tunnel. Ae the temperature of the water and air is being regularly taken at the mouth of the tunnel and several other points, we shall he able to learu exactly what difference the cold water makes as soon as they commence using it.

THE Oswego Iron Works are reported sold to the Oregon Railway and Navigation Company, together with a large amount of real estate, comprising timher land, etc. Villard proposes to erect rolling mills, to give additional facilities for turning out iron.

The Prospects at Tombstone.

The Tombstone *Epitaph* says: When one statee that the outlook for the permanent prosperity of Tombstone is hetter now than ever, the question naturally arises as to the whys and wherefores. We answer: First, hecause the greater development of the mines, upon which all business is based. In Contention, there has been developed above the 600 level, ore sufficient to keep 40 stamps in steady operation for three years. This we have upon the authority of the managers of the mine. The result of the recent compromiee with tbe Flora Morrison has heen to decide the company to build a 40-stamp mill at the mine. This one fact is sufficient to give an assurance of increased prosperity to all branches of husiness.

In the Tombstone company's mines, there is now developed hodies of ore that aggregate 35,000 tons, from which the stockholders may reasonahly expect another million dollars in dividends. This development ie confined to thres of their eleven mines. When they shall see fit to open up the remaining eight, all of which show unmistakahle evidence of richness, there is no computing the amount of wealth in store for the fortunats owners.

Grand Central is proving itself a veritable Pactolus, from which streams of wealth flow forth in copious ahundance to make glad the enterprising men who have laid broad and deep the foundation for future successful workinge. Girard, with its 20-stamp mill rapidly assuming form, at our very doors, whose stamps will make music on or ahout the first of January, is and other element of proeperity. The Vizina will soon he in a positiou to augment her present very respectahle monthly output, and Ingersoll, with the $200,000 piled upon ite dump, and which is heing added to at the rate of $1,000 per day, a lds other sources of dependence. Then there is Head Center, Sulphuret, Tranquility and Stonewall, that are not to be omitted in this count, with Wedge, Prompter, Anchor, Emerald, Grand Central South, Grand Dipper, Green Cloud, Winfield, Old Guard, and scores of othere rapidly coming on, to augment the productive mines of an area of two miles square immediately adjacent to the city.

To add to the value of thsse developments and bring the reduction works home to our doors, is the increased water supply. In addition to the two companies already furnishing water through pipes, there is the Huachuca company, that will have its pipes laid and the water flowing at the rate of half a million gallons daily, eome time in January next, and the Sulphurct supply, which will bs ample, it is thought, to run the Girard and Contention mills and adjacent hoisting worke. This copious water supply is destined to play as important a part in the future greatness ae almost any one item.

Last, hut not least, will be the building the main line of the Atchison, Topeka & Santa Fe railroad directly through the city, which will give us the henefit of more and cheaper lumher, wood, coal, merchandise and provisions from the eastward, as well as attracting the business of northeastsrn Sonora, to our doors for its supplies. This is no fancy picture, hut one that can be verified to the satisfaction of any husiness man who will take the time and trouhle to investigate the snhject. Never in our knowledge did a place have a hrighter outlook than Tomhstone at this time.

Hite's Cove District.

The Hite Mine.

Tbe Hite mine is showing up first-class below the 900 level. The vein in the hottom of the new two-compartment shaft, which is heing sunk from the ahove level, is of good size and very high grade. The work at this point of the mine has not heen progressing very rapidly, ae all hoisting is done hy hand. As soon as the new turhine wheel arrives, which is to furnish the power for the air compreseor, rock drills and hoisting works, the shaft will he put down as rapidly as powder and compressed air can do it. The new mill ie kept running night and day. The old mill is undergoing considerahle repaire, and will soon be in fine running order, when we shall expect to hear of some fine clean-ups.

The South Hite Mine.

We learn that the ore hody on the 200 and 300 levele of the South Hite mine is showing up splendidly, the vein heing from two to four ft. in width, and of good grade and character. They are now driving the 500 level west into the Spring tunnel claim, where little or no prospecting has heen done, although the croppings show good ore.

Ferguson Lode.

We learn from correepondents that things look very favorahle at this mine. Work appears to he progressing in a manner that indicates something big after a while.

Simpson and Gordon Lode.

The Simpson & Gordon mine, on Sweetwater, is progressing rapidly, with good prospects.—*Mariposa Herald.*

WE see hy the Wood River *Miner* tbat prospectors are swarming ahout the towns along the river and offering their claims at very low figures for cash. Many of them wish to leave for home or a warmer climate, and others will winter here. It takes cash to keep them until the prospecting field is again open, and this is why they will part with their prospects at reasonahle figures.

Concentrations.

THE Brush dam on Bsar river was evidently set on fire.

THE water coming out of the Sutro Tunnel has a temperature of 120°.

MILLS and mines off the railroad are now getting in supplies of wood for the winter.

THE hoiler of the Empire quartz mill hlew up the other day killing the mill hoss James McGregor.

IT is claimed that there is a mountain of copper and iron ore in the district east of Loveland's station, Nevada, which has not yet heen much prospected.

WM. B. HYDE, formerly connected with the C. P. R. R., hut lately manager of the Gen. Custer mines, Idaho, has returned to his home in Oakland.

THE little water mills on Gold canyon, from Gold Hill downward, are gradually resuming work. Most of these reduce ores taken out of small mines in Devil's Gate district.

BULLION to the amount of $462,412.27 was shipped from Tombstone during the month of Octoher. Since April this district has added $2,741,673 49 to the wealth of the country.

THE Tombstone *Epitaph's* mining report shows that the Grand Central mine, for six monthe' run of the mill, has turned out $848,176 in hnllion, from working 18,000 tons of ore.

C. H. JONES, of El Dorado county, died last week. Mr. Jones was for many yeare tbe superintendent of construction and general agent of the California water snd mining company, and its predecessor, the California water company.

THE Eureka Con., Nevada, pays its "trihuters" $2 on $30 oro, and 50% on all ore assaying ahove that sum at the chutes. There are prohably more men engaged in trihuting on the Hill than ever hefore.

THE consolidation of two of the heaviest mining enterprises in New Mexico hae just heen effected in Las Vegas. The properties thus confederated are the Socorro and Mille tunnels in the Socorro mountain.

THE Clipper Gap iron mine is temporarily closed dowu, owing to the want of sufficient coal with wbich to run it. Wheu the kilns now in process of constructiou are completed, there will he 26 in all.

THE only difficulty in the matter of saving the valleys and the hydraulic mining industry is the cost of proper dams. Millions of money can he profitably and economically devoted to this purpose hy the State or nation.

A VEIN of mineral hss heen discovered in Ontonagon county, Wisconsin, on the survey of the Wisconsin, Lake Shore and Western Railway, which aseays 60 % of lead and 15 ozs. of silver to the tou. It will he developed hy Boston and Milwaukee capitalists.

EIGHT hars of hullion, valued at $9,870.20, have been received at Wells, Fargo & Co's offics at Winnemucca from Idaho. Three of the hars, valued at $2,881.54. from the Monarch mine, at Atlanta, were shipped East, and the rest were shipped to San Francisco.

THE Wood River *Miner* warne etrangers against that class of prospectore who have failed to locate any mineral bsaring claims, in order to make a etake for the winter will resort to all sorte of suhterfuges; for this class ie plenty now that winter is coming ou.

WHILE John Treanor, driving one of Seeley's teame, was hauling 100 kege of powder to a mine at Badger hill, Nevada county, a hridge gave away, and the whole outfit was precipitated into the cut. One of the six horses was killed, and Treanor hadly hurt.

MR. G. D. DOUGLAS, agent for the Hecla & Calumet Copper Co., Lake Superior, is at present in Arizona Territory examining the copper interests and gathering statistics relative to present and prospective supply of copper hullion from Arizona and New Mexico.

AT the present time, Enterprise, Great Gulch district, Fresno county, hae a population of ehout 150. New-comere arrive every day, and should the present mining hoom continue, this section of Fresno county is destined in the near future to he one of the livliest in the State.

THE *Herald* says Phœnix, Arizona, is to have a 100-stamp quartz mill built upon the Phœnix mine, near that town. It is expected that shipments of hullion aggregating $75,000 or $80,000 will he made monthly when the mill is completed. The mine is free gold quartz, in slate.

THE bed of Prairie creek recently hroke through into one of the mines of the Chicago, Wilmington & Vermillion Coal Co., in Illinois. The hole thus made is about 200x400 ft. Only four men were in the mine when the hreak occurred, and all of them escaped. The loss to the company is estimated at $100,000.

SAYS the Santa Barbara *Press:* From the oil region of the Santa Clara valley we have news of great activity in that product. Work is active, and drillers command $4 per day. New wells are going down in many directions, and there is increased development, excitement and confidence on all sides.

BY the new arrangement of air pipes, the clearing out of leading drifts and other improvements that have been made in the California and Con. Virginia mines, in connection with the suction fan at the old Con. Virginia shaft, the ventilation is heing wonderfully improved. Already the lower levels are quite comfortahle.

MECHANICAL PROGRESS.

Painting of Cement and Plaster.

Much difference of opiuion prevails respectiag the queetion of paiatiag Portland comont, aad we have eeen work painted a few weeke after the cemeat has set, which has stood well. There is oae poiat which hae a great deal to do with the question of succcssful painting, namely, the absorbency and dryness of the brickwork itself. Many aew walle, saturated with moisture, are comented, and in thie condition no paint can possibly stend if laid ou too soon. It ie a good and safo rule to enforce that Portland cement work should not bo peiated within a year of its oompletion, to allow it to dry thoroughly; but we are safo ia sayiug the majority of new froats are painted hefore they have hoen fiuished threo months. A very desirahle prceeution seems to be to coat the work with linseed oil first.

The painting of plaster work requiros the same care, and the lime works out in small huhbles, destroying thopaint. In painting plaster, white lead and linseed oil, with a little drier, ie recommended hy onc authority. This coat should be of the coasistenco of thin cream, eo thet the oil is ahsorhed into the pleeter in a few hours. In a day or two another thicker coat may ho applied, and a third a few days after, rather thicker, followed hy the haiehiag coat. Foar coats are not too much for good work. By the absorption of the oil into the plaster the surface becomes hardened, and mey ba washed. Aaother method to facilitate this aheorption is followed by paintere, which is to give the plaster two or three ooats of boiliag linseed oil, and thea to apply the other coats of peint. We are incliaed to think the application of the oil hefore the paint a hetter plaa, to iasure a thorough eaturation of the material. The color of Portland cement, and the uaeven tint it sometimes aesumes, is the main reason why paiating is resorted to. For this reason we thiak it may he worth the attention of manufacturers to turn their coasideration to the enbject, and those usiag cemeat ae a stucco might also prevent a hlotchy end uneven tint by attendiag to the preparation of the wall and the sand they use with the cement.—*Building News.*

THE "LONDON" GAS ENGINE.—The popularity of the gas eagine, great as it undoubtedly is already, will, we think, he greatly extended by the introduction of the engiue now being manufactured under Hutchinson's patent hy the London Gas Engine Co. The design and arragements are quite new and original. An oval shaped iron casing of considerahle thicknees, cast in one piece with the cylinder, conceals the piston-rod, connecting rod and crank from view, and while imparting to the engine great firmnces and steadiness, prevents the riek of accideat. Regularity in working ie also attained by the employment of a specially heavy fly-wheel. All parts of the "London" engine are constructed to gauge, and are therefore interchangeahlo and easy of adjustment. The working parts are few in number, and are made of berdened eteel so as to secure the utmost durability and emoothnese of motion. Thc coneumption of gas ielow, and can he regulated with great nicety according to tbe load on the engine. A two-man power engine, working at full power, consumes, on the average, three farthing's worth of gas per hour. Coal, petroleum, atmospheric, or water gas can he ueed equally well. A turn or two of the flywbecl hy hand will set the engiue going, and a hoy or lahorer can attend to it. It is, moreover, very compact and portable. The one-man engine, for instance, occupiee a floor epece of two ft. four inchee by one ft. 10 inchee, and etande three ft. 11 inches high, and weighs four and one-half cwt.—*Ironmonger.*

BRAIN POWER AND MACHINE WORK.—The day of hrute force in the machine shop hae gone hy. The entire operations to-day are more of the hrain than of the muscle, and since some ono must furnieh tho braiu work, it is a pertinent question for the individual machiuist whether he shall educate himself to supply the larger part of it, *and get paid for it*, or whether on the other hand he ehall put himeelf nearer the level of the mechine he operatee, and allow some one elee to get paid for thiaking. This is a matter the mechanic has to eettle for himeelf. —*American Machinist.*

RESISTANCE OF STEEL TO FRACTURE.—Experiments have frequently heeu made, and numherless speculatione have heen indulged in, with referenco to the iafluence of temperature on the reeietance of steel to fracture. The *Moniteur Industriel* states that the chief ceuse of variation in strength is the preeence of sulphur; eteel or iron containing no su phur maintain the eame hreakiog strain at all observed temperatures, the only change being a trifling variation of the limit of elasticity.

TO DETECT A FLAW IN IRON.—If a piece of iron appears to have an unsound weld, or if it hae a crack apparent upon the eurface and it ie desirous to know how deep it penetrates, heat the part to be teeted to a red heat and pour a hoe etream of water on the faulty spot, but mainly on one eide of it, and the iron on that eide will lose its redness more rapidly than the other side, and plainly indicate how deeply the defect extende.

The Bursting of Saws.

When tho shaft nf the Cunard etcamship *Catalonia* recently broke, aad the vessel wae nbliged to retnrn to New York for repairs, tho captain was interviewed, and asked to give an explanation of the cause of the accident. He could, says the *Northwestern Lumberman*, give nn reasou for it. Mr. Roach, the enperintendent of the iron works where tho shaft was made, was also iaterviewed, and tho conversation led to a generel discussion of the lasting qualities of irnn. Mr. Roach said that iron had its time of usefulnoss juet as men and horses have. That time completed, the iron must be born agein. as ie were.

Railroad mea uaderstaad this law, and know how much weight their froight care will carry, aad estimato how meny milee they will run hefore the wheels aad axles will give out. When the shafte run ont their natural livee, they are thrown aside, though there may he no vieihle defect in them.

Iron has a way of crystalizing in tbe process of time, and often when a piece of it breake, one can find no flaw in the material—no apparent reason for its giving away. It has hcen held hy engineers and scientiste that a constaat vibration of iron disintegretes it, the infirmity becoming pervasive throughout the mass of metel. For this reaeon iron bridges have beea supposed to have a limit of endurance and eafety, and it hes heen predicted that the time will come when the Niagara suspension bridge, hy reason of the constant vihration caused hy paseing traias, will outlast ite cohesive iategrity, and suddenly go down, probably while a weight of valuahle life is passiag over it.

Thie mortality in iron snd eteel, under vihratory influence, may account for tbe bursting of circular saws, which often cauees sad hevoc of life and limb in mills. The intense vibration of the dizzy steel, by reasou of its long use, at last hriags the inevitahle weakuess, and it suddenly flies in pieces. If sawyers could arrive at some definite knowledge ae to the life of a circular saw, as the railroad men do as to the endurance of axlee and wheels, many serious accidents might he avoided.

A NEW WRIST PIN OILER.—For yeare American mechanics have heen showiag their ingenuity in devisiag lahor and capital saving machiaery. The succees that has heen met with by them is truly marvelous, and is plainly discernible hy their use in the differeat manufactures of thie country. Among the prominent and late achievements in the field of invention is Jewel's patent automatic wrist pin oiler. This device is ueed for oiling crank pine, guides, conaectiag rods and pillow hlocks of eteam engines, and is placed on the market hy Messrs. Fairhanks, Morse & Co., Chicago, who claim for it easy application to any style or make of engines; that it is simply positive in any place where attached, effectinga saving of from 75% to 90% of the oil used by an oiler heretofore placed on the market. That it is impossible for a hearing to heat or wear where it ie used, as the oil is forced in regular quantities at regular intervale to the part or point required. It is a well known fact that all engineers are required to use oil in abundance on the main heariogs of their engines, and should they he called away hy other dutiee their oiling ie a eource of anxiety until their return. These oilere relieve an engineer'e mind from all anxiety on theee points, ae the bearings are oiled regularly and no more oil is delivered than ie necessary to keep them properly lubricated. They can he adjueted in a moment to feed fast or slow, and the uniformity of feed is equally positive in otber casee.

FINE DRILLING.—Prof. Edward C. Pickering, of Herverd College, says that in undertaking to measure the intensity of the light of the eatellites of Mars he had occasion to need an extremely small hole. Among the artieans who eseayed to furnish what was required was one who had succeeded in making a hole edgewise through an old fashioned three-cent piece, and and another who had pierced a needle through from end to eud. A hole about the 25-100 part of an inch in diameter was finally eecured.

TREATMENT OF NEW FILES.—A new file should be ueed with a light preseure until the very thin sharp edgee are worn off, after which a heavier preseure may he ueed with much less danger of the teeth crumbling at the top or hreakiog off at the hase. Every filer ehould keep a partially worn file to use first on chilled eurfacee or gritty ekin of castings, or on a weld where horax or eimilar flukes have heen employed, or on the glazed eurface of sawe after gumming.

IRON RAILWAY SLEEPERS.—Spanish papere are at present etrongly arguing in favor of the iutroduction of iron and eteel eleopere for railways. The wooden eleepere employed there now are obtained from foreign couutries, while those of iron and eteel could he manufactured in Spain. The *Gaceta Industreal* estimatee the probahle demand for the first 10 yeare to be 500,000 tone, the manufacture of which would yield an income of 20,000,000 france.

RED ANTS.—The judicioue ueo of oil of turpentine will effectually exterminate red ante. It may he injected into cracke and crevicee in cloeete and elsewhere from an ordinary sewing machine oil can.

SCIENTIFIC PROGRESS.

Molecular Attraction.

F. D. Brown, B. Sc., in a recent scientific paper, says: That if we regard chemical affinity as neutralized hy tbe nuion of two elements, we aro then nuahle to acoount for the reactions takiag place between moleculee, and involviag an interaction of atoms composing different molecules. If, however, the act of combination he regarded ae producing no change in the chemicel forces, aad it he euppoeed that the same attraction is exerted between any given pair of atoms witbout regard to the state of combination of one or hoth of the atoms, then a reasonahle account can be given of chemical reactions, and the existence of molecular combinations does not appear very remarkahle. Further, we are provided with a more or lees effective explanation of the relative volatility of subetaaces. Reasoning from this point of view, and coasideriag the carhon compounds specielly, the author concludes that intermolecular attraction ehould he greater in an acid than in a corresponding alcohol; greater in an alcohol of high molecular weight than in a homologue of which the molecule is less complex; greater in a primery alcobol than in the secondary or tertiery ieomeride; and finally, greeter in a chlorinated compound than in the correspondiag eubstaace containing hydrogen. If the volatility of a suhstance he a measure of the forces of attractioa hetween the molecules, then it muet he admitted that the hoiling points of organic compouads show with some reaeon that the ahove expression represents the value of intermolecular attrection. From this point of view the etudy of the latent heat of many carhon compounds would materially aid us in the eolution of the prohlem of chemical affinity.

The Nature of Coal.

Meesrs. C. F. Cross and E. J. Bevaa, says the *Journal of Gas Lighting*, have recently been carrying on a chemical research iato the nature and method of the formation of coal. They treated jute fiher with sulphuric acid at 70°, and ohtaioed an insoluble, hlack, epongy suhstance. This formation is in some way hased on cellulose and dextriu. The productions of thie epoagy substance is uenally of a destructive character, attended with the evolution of carhonic acid and the formation of ecetic acid. A study of the chemical properties of the suhstance has led the above named observere to the conclusion that lignin is derived from cellulose by chemical modification. A remarkable circumstance in connection with tbe phyeical nature of the hlack euhstance in question is that it dries to a hard mass, reeemhling cannel coal, with which it has heen compared, and similar results of chlorination and nitration have been ohtained. This evidence goes in further support of the opinion that coal is not carbonaceous in any more special sense than alcohol, hut ie rather, as supposed hy Balzer, composed of a eeries of C, O, H, N hodies, which are geneticelly if not homologouely related. It is suggested that cellulose, lignite, peat, coal and authracite are terms of an infinite series specialized hy the conditione of their formation.

THE CYCLE OF THE SEASONS.—Different men of science in England hold different opinions in regard to what ie called "the cycle of the eeaeons." E. J. Lowe said, in 1879: "There can he no reasonable douht that a cycle of eeasone exiets, though its precise period has yet to he aecertained. A lengthened inveetigation has, however, eatisfied me that the cycle is ahout 11 years. Thus, every 11 years drouth and heat are experienced, uenally of three yeare' duration —that is to say, the drouth recurring in three coneecutive summere." And in the same year, Mr. Roe, F. R. A. S., broached a theory cloeely resembling Mr. Lowe'e. G. T. Ryves, F. M. S., now calls attention to the fact that the last three summere, which, according to the theory, should bave heen hot and very dry, have, on the contrary, heen cold aud wet, and from thie he drawe the conclusion that at heet euch predictions are hut scientific gueeses, and when put forth as propheciee they are not only sure, in many casee, to disappoint those who put faith in them, hut are apt to create a false impreeeion in the puhlic mind as to what is attainable in the present etate of meteorological science. On the whole, it eeems that any such predictions, no matter who makee them, are not a whit more likely to be verified than if Mr. Venner had made them.

THE LIGHT OF THE STARS.—For a numher of years the epecial work carried on at the Harvard observatory, under the direction of Prof. Pickering, has been the meaeurement of the intensity of the light of the heavenly hodies. Some of the reeulte presented at a recent meeting of the Society of Arte, at the Institute of Technology, Boston, indicate measurements almoet incredibly finc. The light which falle upon the earth from tho eatellites of Mare, for example, is ahout equivalent to what a man'e hand on which the eun ehone at Washington would reflect to Boston. The lahor of measuring the hrightneee of all the visihle etare wae hegun two years ago. It hae eince gone on at the rate of about 40,000 a year, and will he completed next fall.

Climate and Altitude.

Tho Virginia City *Enterprise* (Nevada) furnishes the following: "The relatione of climate to altitude are very intimete, but in most regions are not apparent—that ie, not visihle to tho eye. Hero, however, it is different. For instaace, yesterday (Novemher 15th) while all tho hills and mountains round about were arrayed in robes of dazzling white there was in the center of the eastern landscape one hig spot of brown. This was on the Carson river, down toward Fort Churchill. There not only tho valley lend, but also all the low borderiag hills remaiaed a deep and deeolate hrowa. It was like a dirty spot left in the middle of a newly whitewashed wall. Although this epot is at no great distaace from this city the people thero walk about oa hare ground, while here we wade in a foot of enow. With them it is only late autumn; with us it is genuine winter. However, they have not far to go to get a taste of winter Half a mile from their homes would take moet of them up intn the saow belt.

Persons who have lived all their livee in prairie and other level regions have but an indistinct notion of the great influence altitude has upon climate. When their plaias are hare, they do not know that winter is often but 100 ft. above their heads.

In this mountaiaous region we have an excellent opportunity of etudying the effects of altitude. It ie sometimes quite wonderful to observe the eveaness of the snow line. It ie drawn midway up the face of the whole line of hills as neatly as though marked with a chalkline. Sometimes it is higher, sometimes it is lower, owing to the temperature. The evenness depeads a great deal upon the air. When there is much wind the snow line is not well defined, hut when it is calm the strata of the atmosphere are perfectly regular. The snow line is then as level as though it were the water line of a lake.

Frequently, when no snow lies on our etreets, we can see on the slope of Mt. Davidson, only 200 or 300 ft. above us, the line separating us from the region of winter.

A Beautiful Sight.

The same paper, as above quoted, givee the followiag under the head of "Snow Streamers:" "The peak of Mt. Davidson last evening presented a moet wild and wiatry appearance. The snow streamere were ahroed in all their glory. Last eveniag, however, they could hardly he called streamere. They were in reality an unending series of whirlwinds that chased each other aloag the crest of the mountain. The epiral columns of snow took a thousaad shapes in forming and vanishing. Being etrongly lighted hy the setting eua, the great eurgiag columns looked like whirls of flame and illuminated emoke rolling up from a great fire. This hrilliancy was seen in places where the rays of the sun passed through the thin mist of a single snow whirl. In placee where three of four columns happened for a moment to fall in line hetween the spectator and the sun, the whole was black as the smoke from the funnel of a steamhoat. Frequently eeveral of the colors of tho rainhow would flash out around these dark columns, and a moment after all above tbe peak would he deep red, giving the top of the mountain the appearance of an active volcano. It would have heen a fine opportunity for a scientist interested in the study of atmospheric currente. The motions of these snow whirls show us what is alwaye taking place in the air at the top of the mountain, hoth winter and summer, and if on our mountain, doubtless on all mountains of like hight. The straight current of the atmoephere ie hroken up into thousande of little whirlwinds that riee from 50 to 200 ft. ahove the eurface of the ground.

PREVENTING WATER FROM FREEZING IN HYDRAULIC APPARATUS.—The growing uee of hydraulic machinery for riveting, flanging, etc., in our iron worke, and for elevators, hoisting machinery, cranes, etc., mekes the question of avoiding the danger incideut to the freezing of water in the pipee an important one. The *Engineer* statee that in Eogland there is no generally adopted method. An admixture of methylated epirits, salt or glycerine has heen tried, and Mr. Tweddell, well known in connection with hydraulic machinery, made some experiments on the effect of the addition of glycerine. In open vessels, at a temperature of 28°, when pure water froze rapidly, only a lump of rotten icewas formed when 1% of glycerine was present, less still with 2%, the ico formed not being sufficiently solid to flow, eepecially with a preesure of 1,500 lbs. per square inch. One firm found that in addiug one gallon of glycerine to 300 gallons of water no trouble whatever was experienced, while another firm usee 25%, although they helieve 10% to be enough for ordinary purposes. Salt ie much cheaper, hut while glyceriue rather preeerves leather packings than otherwise, common ealt destroye them, especially wheu in cast iron.

AN OBSERVATORY FOR BOSTON.—Mr. Miller, Preeident of the Atlantic Iron Works, Bostou, with eeveral other gentlemen, have determined on the erection in that city of au iron observatory, which, it is eaid, will he the highest structure in the United States. The models, plane, etc., have all heen completed. The etructure will he built of the heet iron adapted for euch a purpose, and its general appearance will he both ornamental and imposing, at the eame time combining safety and comfort.

The Mining Share Market.

Stocks continue bad. In fact, it seems as if the loss of interest in them is, while gradual, so sure that they would drop out of sight altogether in time. Our tables show the variation in prices.

To show what work is being done on the Comstock, we take the following from the Gold Hills *News:*

Following is the whole number of men employed at the several north end mines, from the Con. Virginia on the south to the Utah on the north.

Utah—Miners, 24; surface men, 18; total, 42.

Sierra Nevada—Miners, 76; surface men, 14; total, 90.

Union shaft—Miners, 45; surface men, 61; total, 106,

Mexican—Miners, 39.

Union Con.—Miners, 63.

Ophir—Miners, 70; surface men, 19; total, 89.

California—Miners, 28; surface men, 1; total, 29.

C. & C. shaft—Surface men, 43.

Con. Virginia—Miners, 17; surface men, 3; total, 20.

The large number of surface men at the Union and C. & C. shafts is accounted for by the fact that they do the surface work for several mines, and it will be observed that some of the companies, as the Mexican, Union Con., etc., have no surface men. Among the surface men are included carpenters, blacksmiths, engineers, ordinary laborers, clerks, attorneys, etc. It is also probable that some of the so-called surface men, as attorneys, surveyors, etc., are counted over and over in going through the list of mines. However, all told, the several mines in the list foot up but 538 employees.

From this it will be seen that a vast deal of work is being done with very few men, the total number of those put down as miners being 362 men.

Thus, it will be seen that all the drifting, crosscutting, sinking of winzes, drilling, cutting of drains and many other kinds of underground work from the Con. Virginia northward, is being done by the small force of 362 men.

Stockholders have no reason to complain of extravagance in the way of employing workmen. When we consider the vast amount of underground work of all kinds that is daily and weekly accomplished by these 362 men, we can see that they do but very little "soldiering."

Frue Concentrators.—Four Frue concentrators have been sent to Mr. Grayson's Brown Bear mine, Trinity county. Tailings now go $1.50 per ton, the ore running $30. Henry Janin has also bought two for the Minas Nuevas Mining Co., near Alamos, Mexico. J. B. Haggin has sent four for the famous Joquistita mine, Mexico. The ore from this mine runs $300 per ton. L. Charronat has purchased two for a mine at Nevada City. Several of these concentrators have gone to Cherry Creek, Nev., to concentrate the refractory sulphurets of silver ore below the battery. The tailings containing the chloride then become free milling ore, the expense of dry crushing and roasting the whole mass being thereby saved.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Puget Sound Iron Co.—Nov. 19. Capital stock, $500,000. Object: To carry on the business of making, manufacturing or purchasing iron or steel or other metal in California, Washington Territory or British Columbia Directors—G. W. Prescott, J. H. Redington, J. A. Paxton, D. B. Hinckley, C. H. Simpkins, C. F. A. Talbot, A. Ambot.

Regent M. Co.—Nov. 16. (Virginia City, Nev). Location, Nevada. Directors—M. C. Hillyer, C. L. Weller, T. W. Hubbard, L. D. Folsom and Joseph F. Angel. President, M. C. Hillyer; Vice President, C. L. Weller; Secretary, T. W. Hubbard; Charles Elliott, Transfer Secretary, San Francisco; George B. Hillyer, Superintendent. The Regent Co. have 1,500 ft. of ground at Silver City, Lyon county, adjoining the Lower Comstock, and absorb all the leases, etc., from the Royal and Lower Comstock to the Emigrant Prospecting Co. Thus all these different claims—Royal, Lower Comstock and Emigrant Prospecting Co.—will hereafter disappear and all the ground will be known as the Regent. In the last two months the mine has produced nearly $50,000 in bullion, and they are now hoisting and sending to the mill 40 tons of ore per day.

Carson & Colorado R. R. Co.—Third Division—Nov. 19. Capital stock, $9,000,000 in 90,000 shares. Directors—H. M. Yerrington, D. A. Bender, J. H. Dobinson, Wm. S. Wood, D. L. Bliss, S. P. Smith, M. B. Langhorne, all of whom except S. P. Smith subscribe for ten shares of stock each. S. P. Smith, another name for D. O. Mills, subscribes for 1,980 shares, and he has been elected Treasurer of the corporation. The proposed route, on a narrow-gauge track, is from McBride's station, Mono county, the southwesterly terminus of the Second Division, thence by way of Owen's valley and across Mojave Desert to a point in the main line of the Southern Pacific railroad at or near Mojave station, Kern county; an estimated distance of 204 miles.

Meetings and Elections.

Curtis Cons. M. Co., Nov. 18: Directors—John Sedgwick, A. C. Hiester, J. W. Hussey, H. S. Stone and W. M. MacMillan. Officers—A. C. Hiester, President; J. W. Hussey, Vice-President; H. S. Stone, Secretary; David Wilder, Assistant Secretary; Bank of California, Treasurer.

Mammoth Gravel M. C., Nov. 18: Directors—Thomas H. Blythe, L. H. Varney, Thomas D. Diune, Thomas W. Nowlin and William H. H. Hart, who organized by electing Thos. H. Blythe President, L. H. Varney Vice-President, Thos. H. Nowlin Treasurer, and Wm. H. H. Hart Manager and Secretary.

Jumping of Mines.—One of the first topics which Congress will take up when it meets will be the amendments of the mining law. From its action last year, it may be inferred that neither Judge Belford's bill, which received the unanimous approval of the two committees on mines, nor the subsequent hill, which was published last winter, will readily receive the assent of Congress. Yet something ought to be done. Some measure ought to be devised to stop the business of jumping. It has become a regular trade here, in which some of the worst men of the community are engaged, knowing full well that they can always sell their jumper's title—if not to the parties whose property they have jumped, to some outside speculator. There are plenty of men with money in Leadville who are ready to buy a jumper's title if the property promises well. The new law ought to protect a poor man in his rights to the property on which he has spent his money and his time, without having to guard over it with a shot-gun.—*Leadville Circular.*

In the main south drift on the 2275 level of the Overman they are feeling ahead with the diamond drill to guard against water. Some hot water had commenced coming in at the face of the drift before the drill was started.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Kennedy.—Amador *Ledger*, Nov. 19: The mill suspended operations last Saturday. There is nothing doing around the mine except bailing water out of the shaft. How the rock lately crushed paid we are unable to say.

Plymouth Notes.—A Burleigh drill was sent down the north shaft of the Empire on the 15th. It will be in running order in a few days. Fifty-five stamps are kept in motion at the mill.

CALAVERAS.

Hydraulic.—*Mountain Echo*, Nov. 10.: We learn that a hydraulic is soon to be erected on the celebrated Gold Hill mine at Smith's Flat, the proportions of which though small will add greatly to the facilities for the successful working of the mine. The length of the main pipe will be about 800 ft, as to size we are not informed. This mine was first discovered some 23 years ago, and the surface was immensely rich as well as the quartz. It is the intention of the present owners, Osborn & Sou, to commence operations in a short time.

Rawhide Ranch.—*Mountain Echo*, Nov. 15: Rawhide is not very lively just now, but gives promise of a vigorous future, when the various quartz mines in the neighborhood are more fully developed. The Mother lode, as you are probably aware, runs directly through this place, and there is no reason why all the claims located along the line should not prove of value when more thoroughly developed. That they are likely to prove such, is shown by the success of the Gem and Alabama mines situated about three-quarters of a mile northeast of this place. Though the mills are now shut down, owing to the lack of water, operations will be resumed as soon as the water is turned on. These mines are understood to be in a flourishing condition, especially the former. The Gem is owned by Mr. Harris, the Alabama by Mr. Harris and Gen Gashweiler of San Francisco. One peculiarity of these mines is that the most work has been done and the richest ore found, not in the large vein known as the Mother lode, but in the small veins to the east of the parent vein. Coming this way lie the Hooker and Rawhide two claims now owned by the same parties, but upon which no work of consequence has yet been done. Next in line is the old Rawhide mine. Some prospecting is being done toward the northwestern extremity of this claim by Mr. Haydock, who has the mine in charge at present, and it is likely that extensive operations may be commenced before a great while. This claim has a first-class mill, at present in a state of disuse, and is considered by many one of the most promising mines in the country. Running northeast toward Mormon creek are a number of claims, one of which—the Tarantula, owned by Mr. Frisbie—is now being prospected. This is something of a pocket country, too, a number having been found, but you needn't get excited and come over here on that account, for the Mother lode is located from the Stanislaus to the Tuolumne, nearly all the surrounding country is plastered over with patented ranches, and what is left I claim. What we want here is not prospecting, anyway, but capital—men with means and energy who will develop mines, build mills, bring out natural wealth, and make things howl generally.

EL DORADO.

Grizzly Flat.—Cor. *Mountain Democrat*, Nov. 12: Mr. Lyon is pushing ahead at the Driesbach mine, and has sunk a shaft over 30 ft. It is in old ground and he does not expect to strike a ledge for some time. He is now about to let a contract for sinking another shaft 150 ft deep, and as they now have a boarding house completed on the ground, Mr. Gignac can give his whole attention to the management of the mine. The Melton mill is running steadily on rock from one of Driesbach's mines, and from present indications the result will be most satisfactory. The contractors of the Treat mine have finished their 100 ft contract, and it is understood that work will go right along for further developments. Mr. Bullard will start his mill on the Sacramento mine during next week if water can be had. At the Eagle mine they are working two shifts, running tunnel on ledge. At the Mount Pleasant the new mill is completed and during the week will crush about 10 tons of rock as a trial test. The new hoisting works are about completed, and Supt. Smith has men now putting a cage in the shaft. From present appearances, everything will soon be in order, and the mill will be kept running permanently. They are laying in a large supply of wood, timbers, etc.

Another Good Quartz Ledge.—*Mountain Democrat*, Nov. 19: Messrs. F. M. Bickerhoff, F. H. Goyan and A. H. Reed have been drifting in the claim at Ringgold, known as the "Judge Reid claim," and have struck a large and strong ledge of very handsome quartz that gives a fine prospect and will pay at least $30 per ton by mill process.

New Mining Superintendent.—Prof. Thos. Price came up from San Francisco last Wednesday, accompanied by Mr. W. A. Jones, the newly appointed superintendent of the Pacific mine, who takes the place of Mr. Isaac Thomas, recently deceased.

Another Gravel Mine.—McGinnis and Wheeler, at Fort Jim, are running a tunnel and otherwise opening up for systematic operations a bed of gravel that gives very fine prospects.

The Highville Mine.—The now mill on the Highville mine, near Newtown, Patterson superintendent, started up last week and is crushing gravel of extra good quality. In this mine, besides the fine gold that permeates a thick stratum of gravel, it has been common to find in the crevices and on the bedrock a considerable amount of coarse gold. In some instances chunks have been found that weighed from $200 to $300. A few days ago, since work was commenced under the present management, a nugget of solid gold was found which weighed a fraction over 3½ ozs.

Enormously Rich.—The mine at Pleasant valley, commonly known as the Gross mine, recently purchased or bonded by J. E. Lyon, has been turning out some enormously rich ore within the last week. It is from a shaft that is being sunk on the new ledge, which shaft is now down about 30 ft below the bottom of the tunnel. This new ledge was discovered by following some exceedingly rich stringers that made off to the southwestward from the main ledge. The ore taken from the shaft has all been good, ranging from $200 to $500 per ton, but latterly it has been improving, and that taken from the bottom is thickly flecked with gold, and is estimated to be good for fully $1,000 to the ton. The ledge is about 3 ft thick, beautifully ribboned, and the sulphurets are very rich. Mr. Lyon's experience in Colorado has made him more a smelter than a miller of ore, and has convinced him that the smelting process is proportionately much more profitable when applied to high-grade than in the case of low-grade ores, and therefore he has determined to sack this rich ore and send it to San Francisco to be smelted. Already a considerable amount has been sacked, and he has contracted with Mr. Landecker, of this city, to furnish him with a thousand sacks to be used for this purpose.

MARIPOSA.

Mining Items from Coulterville.—*Herald*, Nov. 19: We learn that Messrs. Hulings & Shreve, the President and Treasurer of the Mariposa Quartz and Lumber Mills and Mining Co., are operating on the Malvena quartz lode (or series), which is a parallel vein of the Mary Harrison vein (or Mother lode). The tunnel starts on the Potosi and runs under to open the old Malvena. The tunnel is in about 2,000 ft. The ore shows milling rock for 300 ft on the Malvena. The width of vein on the different cross-cuts shows from 4 to 15 ft. The company are preparing to do extensive work, and have a large amount of machinery in transit for their mines in that locality.

A Big Sale.—Mariposa *Gazette*, Nov. 19: A large sale

of real estate appears entered of a late date in the Recorder's office of Mariposa county. The Mariposa Land and Mining Co., of California, sells to the Mt. Bullion G. M. Co., of New York, 12 sections of land, consideration $1, and $12 000 000 capital stock.

THE LATEST MINE.—The news this week from this mine is of a most cheering kind. The stope from the 70 level is producing more gold than at any other time previous, and continues to improve as the work progresses. Free gold is visible all through the vein matter, and is pronounced exceedingly rich.

LOOMING UP.—The extensive quartz mine near Hornitos known as Quartz mountain, at present under the control of the California Developing Co., is producing fine ore in large quantities.

NOT SERIOUS.—The explosion of the small powder magazine, occurring at the mouth of the tunnel of the Hite G. M. Co., one day last week, did but little damage, as we are informed, and nobody hurt.

NEVADA.

DEATH OF BENJAMIN COLEMAN.—*Transcript*, Nov. 19: Benjamin Coleman, aged 45 years, brother of John C. and Edward Coleman, of this place, died in Washington, D. C., on the 28th of October last. Deceased formerly lived in Grass Valley and at Iowa Hill, Placer county, and will be kindly remembered by a great number of friends. He leaves a son, Arthur, who resides here with Edward Coleman.

A HEAVY BLAST.—San Juan *Times*, Nov. 19: On Saturday evening last the houses of this place were terribly shook up by a blast in the American mine in which 27,500 lbs. of black powder was utilized. The blast did immense execution. It tossed up the whole earth 120 ft in width and 100 ft in length into the hill with a bank face of over 100 ft. The mine is now run by the Yuba Tunnel G. M. Co., a corporation. To prepare for this immense blast a drift was run into the hill as near bedrock as possible, 100 ft; at the end of the drift other drifts were run each way 60 ft, making 220 ft in all. Into these side drifts the powder was placed and the main drift tamped. It was all exploded in an instant of time.

PLACER.

MICHIGAN BLUFF.—Placer *Herald*, Nov. 19: From Ed. Thompson, of Michigan Bluff, we learn that everybody there is well and happy, and times lively. The chrome mines near the bluff are being actively worked, and their extent is practically limitless. During the late storm considerable snow fell at that point.

PLUMAS.

MONITOR.—Greenville *Bulletin*, Nov. 19: The Monitor mine is being worked vigorously. Mr. George Comptou is superintending the mine, and has three shifts of men employed drifting on the ledge. The ore looks well, and milling will soon begin. Mr. D. L. McDonald, of San Francisco, President of the Crescent M. Co., is now at Crescent completing arrangements to re-open that extensive and valuable property. A few men are already at work, fixing up and repairing machinery preparatory to the commencement of extensive work in the early spring. A new working shaft will be sunk, and all the old works thoroughly opened and repaired. The Crescent is well known to be one of the oldest and best mines in the district; it has yielded more bullion in past years than any other mine in it, yet has only been worked to a depth of 180 ft. In the bottom of the deepest shaft is a splendid lode, warranting the assurance that when developed sufficiently it will place the mine upon a permanent dividend paying basis. The people of this vicinity have the greatest confidence in the value of the mine, and will receive with much pleasure the news that it is to be re-opened. The Taylor Plumas mine has recently been sold to, and incorporated by, a New York Company. It is located near the Crescent mine, and was formerly known as the Taylor mine. Mr. M. B. Bransford is a large stockholder, one of the Directors and general superintendent. He has a double shift of men employed driving the tunnel into the mountain along the line of the lode, which daily improves, both in width and richness. The face of the drift now shows 5 ft of high-grade ore. Ample means have been provided for developing the mine and building stamp mills and other needed improvements. The superintendent has the greatest confidence in the superior value of the property, and is pushing forward the development of it, as fast as circumstances will permit.

SHASTA.

SUNNY HILL.—Shasta *Courier*, Nov 20: Mining matters at Sunny Hill are going ahead. Dutton & Peck's arastra and Balinu's arastra are both busily engaged in grinding rock. Joe Davis is running a tunnel on his own new strike, and is taking out good ore. C. J. Russell is running a tunnel on the old Alice mine to tap a rich chimney of ore, cropping about 18 inches in width. Grant, of the firm of Knox & Grant, of Bullychoop, has left Bullychoop for the winter, and is now engaged in prospecting in Sunny Hill mining district in company with a Mr. Bumgarner. We understand that all hands will leave Bullychoop for the winter except the parties engaged in running a tunnel on the old Bullychoop ledge—they will remain and fight it out with the great storm king of that section. Bullychoop is a cheerless region in the winter season, owing to its great altitude. Charles P. Summers and Robert Hall will run J. P. W. Davis' hydraulic placer mine, near Eagle creek, this winter.

QUARTZ HILL.—Thos. J. Harrison was in town Wednesday. He has been engaged in sinking a shaft on his quartz ledge at Quartz Hill, and has it down 40 ft. The ore is good, and the ledge which has varied considerably in width as exposed, is 3 ft in thickness at the bottom of the shaft. Other parties who have locations on the same ledge and have been sinking shafts will probably join with Tom, and the combination concentrate their labors on one shaft. Old Quartz Hill once had very rich placer mines and has the biggest upheaval of quartz to be found above the surface of the earth in this county, while small quartz rocks and pebbles, often containing gold, whiten the ground in every direction. Therefore it is believed that the ledges in the neighborhood will prove to contain rich ore when developed.

SLATE CREEK.—Times have been pretty good the past summer and fall in this upper country, and freight and travel has been lively on the road. No big strikes have been reported in the mines, however, for a long time, although the miners' picks continue to sound from Soda, Hazel and Mears creeks to Portuguese flat, Slate creek and old Dog creek. But times have changed, especially on Dog creek, where the remaining diggings are hard to work, and do not "pan out" like they did 20 years ago when the "Five Nation" company (made up of an American, a Pole, a Prussian, a Sardinian and a Frenchman) took out gold by the handful from their claim on the hillside, or even later, when McCall sluiced out the $100 and $200 ebunks, then noted in the columns of the *Courier*. Those were the days, too, when our old blacksmith and others took out a mint of money on old Shenanagan bar, and gave some of it a lively chance at another bar—not that of justice, however.

EAGLE CREEK AND SUNNY HILL.—Preparations are being made for active work this winter in and around Piety hill The Piety Hill Ditch and Gravel Co. have replaced quite a lot of old pipe and "giants" by new ones. About 2 years more will witness the washing away of old Piety hill. The company are within about 200 yards of the town. The Chicago Co. of South Fork, are now engaged in working and prospecting their mine. Other mines and mining improvements are rapidly progressing in that district. Messrs. Lauderwasser & Roussell have now got their silver mine pretty well developed, and are quite well pleased with their ore showing, and are waiting on the movements of parties below preparatory to the erection of proper reduction works.

SIERRA.

TRUCKEE GRAVEL MINING CO.—Truckee *Republican*, Nov. 19: From Supt. C. F. Byrne we have received the following information concerning the condition and prospects of the Truckee gravel mining company: This company has been quietly going along for the past 2 years prospecting for an ancient channel or river bed situated in the northeastern portion of Sierra county, in Gold Lake district, at an expense of several thousand dollars. This is the first company to start into the deep or hill prospecting, on the Mohawk side of the ridge. The surrounding ravine or surface diggings being very rich, the character of the gold being very coarse and of the finest quality, nuggets being found weighing as high as 56 ozs, the flattering prospect being found in the Truckee claim this summer were obtained at a distance of 750 ft in the mountain, where the channel is beginning to come in, the character of gravel at this point being of the heaviest kind of wash, and of an easy, drifting nature. Everything is now shut down for this winter and in readiness for starting in the spring with the first water.

WATER.—*Mountain Messenger*, Nov. 19: The late storm will give the miners considerable water, and make times brisk for our drift and hydraulic claims. The main tunnel of the Bald Mountain Extension Co., Forest City, is being surveyed this week, by the Bald Mountain Co. The storm this week has driven the Chinamen out of the river, here at the forks. This is the third time that the high water has flooded their diggings and caused them to suspend work, yet they are, with their ancient persistency, at it again.

SIERRA CITY.—The new tunnel of the Sierra Butte M. Co. is in about 250 ft and they are in blasting rock. The heatings for the air compressor are nearing completion, and the Burleigh drills will be set to work at an early day. At Loganville, at the Marguerite mine, things look lively. The company at present employ 32 men. The boarding-house and office are completed, and the mill is near under roof. The machinery and timbers for the hoisting works are on the ground, in fact, everything is being pushed ahead as fast as possible under the able management of Supt. Taylor. The tunnel of the Blue Gravel mine is in 650 ft. The property of this company is one of the best around Sierra City; bedrock was struck in the tunnel about 2 weeks ago, and at last accounts gravel is coming in which prospects in fine gold.

NEVADA.

WASHOE DISTRICT.

UTAH.—Gold Hill *News*, Nov. 21: The blower station at the 2500 level is completed and the blower is in place. The east drift has been extended 30 ft.

SIERRA NEVADA.—On the 2700 level the joint Union Consolidated east winze has been sunk and timbered 10 ft, the joint Union Consolidated east drift was advanced 50 ft, and the west drift 26 ft.

OVERMAN.—Drillhole on 2275 level was run on course of drift 185 ft, when the rod broke and we had to abandon the hole.

OPHIR.—There have been extracted from the cropping 228 tons of ore, and bullion to the value of $17,021 56 has been shipped.

UNION CONSOLIDATED.—In the joint Mexican east winze down from the 2500 level are cutting out a station at the 2700 level.

CANDELARIA DISTRICT.

NORTHERN BELLE.—*True Fissure*, Nov 19: The development on the fourth shaft level, mentioned in report of last week, did not prove as anticipated. Ore still shows on the north side of the drift and the outlook is favorable for it continuing down. The general formation in this vicinity is still promising. The other shaft levels have shown no material change during the week. The adit and levels above are not showing quite as well as last week and are not producing quite as much ore. There are being extracted and sent to the mills about 60 tons of ore daily. Both mills are doing the usual amount of work. Bullion shipments for the week ending November 16th, amount to $21,181 57, and aggregate $40,859 26 on November account to the above date.

MOUNT DIABLO.—A drift has been started east, from the bottom of winze No. 1, on the third level, the face of which is in low grade quartz ore assaying from $32 to $39 per ton. The north crosscut from winze No. 3, is in 100 ft. In the intermediate, below the third level, the ledge is smaller but the ore still continues of fair grade. The east drift on the third level has advanced 13 ft It has shown spots and streaks of ore, assaying from $40 to $64, since last report. The winze from the east drift on the second level has reached a depth of 58 ft. The upraise from the west drift, same level, has attained a distance of 42 ft. The winze in the gulch is down 175 ft.

CRABB DISTRICT.

WATER.—Esmeralda *Herald*, Nov. 19: S. Y. Crabb, after whom Crabb mining district was named, paid the *Herald* office a visit last Sunday. He says preparations are being made to take water out of Walker river at a point that will give sufficient fall to run the wheel for the mill which is to be built by H. X. Thompson. The mill is expected to be ready to crush ore by the 1st of March. Only a few men are at work in the mines at present, but active operations will commence next month. A boarding-house has been built at the mill site on the river and is now open for the accommodation of the public. Two houses are in course of construction at the mines. Mr. Crabb thinks they will be shipping bullion in five months.

CHERRY CREEK DISTRICT.

STAR.—White Pine *News*, Nov. 12: At the Star the usual work is going on in the several drifts above the 540 level, and the usual quantity of ore is being extracted, which now shows a higher assay than for several months past. The sinking of the shaft is also progressing satisfactorily. At the Exchange, they are clearing away the ground around the shaft, and doing other necessary work, preparatory to starting operations on a large scale They will also put their mill in order, or what is more probable, erect a new one. The Exchange is a valuable mine, and with adequate milling facilities, cannot fail but prove a source of profit to the owners. The Tecup property is at a standstill. The notes of this company to creditors here fall due on the 20th inst., and it is probable that some of its leading officers will be out from New York at that time and make arrangements to resume work at an early day. They have a good mine and mill, but like most Eastern companies, they expected too much at the outset, and that was what brought on their financial complications.

EGAN CANYON DISTRICT.

SAN JOSE.—White Pine *News*, Nov. 12: At Egan Canyon, the repairs to the San Jose Co.'s mill are nearly completed and teams have already commenced to haul ore from the mine to the mill. The ore stopes in the mine are now looking much better than a month ago, and in consequence the force of miners has of late been considerably increased.

ESMERALDA DISTRICT.

THE CORTEZ MINE.—Esmeralda *Herald*, Nov. 19: The incline shaft has reached the lower tunnel level, and the tunnel is being rapidly pushed to tap the ledge at that point. The intersection will be made some time this month. Work has been commenced on drift No. 1, running west from the upper tunnel. This drift will open up a portion of Silver Hill that has never had a pick stuck into it, and those familiar with the character of ground now being broken in the drift, say the chances of encountering rich ore bodies in that direction are very favorable. Things are running smoothly in the absence of Supt. Wells, under the guidance of acting Supt. Tucker and Foreman Murphy.

RICH ORE.—Recently 20 tons of ore from the Aurora Hill Con. mine, of this place, was shipped to Bodie and worked in the Bulwer-Standard mill. The result was $8,475 05 in gold and $512 07 in silver, making $8,985.12 the total yield of the 20 tons; or, $440.25 per ton. As we have repeatedly stated, and we want it as a mill to show the outside world that we have got mines, and good ones, too.

THE FANNIE GOLDEN.—Ed Greeley has started operations on the Fannie Golden mine. Griff. Williams is superintendent. The tunnel is being driven ahead with the expectation of striking the ledge at no very distant point. But should the ledge be a myth, the Fannie Golden is a good property, for a good supply of water already has been encountered, which could easily be brought into town for use, and would insure a revenue to the owners equal to a dividend-paying mine.

GARFIELD DISTRICT.

LOTTIE.—*True Fissure*, Nov. 14: The owners of the Lottie mine, located in Garfield district, have received returns from a shipment of ore worked by the Lyon M. & M. Co. The first-class ore yielded an average of $1,391.20 per ton; the second class, $954.34. The ore was sacked for convenience of handling, each sack containing 110 lbs. and produced an average of $76 per sack. The owners of the Lottie are deserving of their success from the energy which they have displayed in the rocky, waterless country where it is situated.

SAFFORD DISTRICT.

SATISFACTORY.—Eureka *Sentinel*, Nov 19. We are pleased to learn, from a reliable source, that the developments now being made in the above named district are of a most satisfactory character. The vein on the northeast end of the Onondaga continues in ore of a high grade. In the Mary Ann, a location southeast of the Onondaga, a cut was run on the surface some distance and the ledge struck, upon which a shaft is being sunk. At a depth of 20 ft a body of blue bromide ore, 5 ft in thickness, with well-defined walls, has shown itself. The ore appears to be strong in place and has every appearance of being extensive. At a further depth crosscutting will commence and the bonanza explored. Work on the Alta is being prosecuted with vigor. The shaft is down 25 ft, with ore in the bottom the full width of the shaft. The ore is rich, and the prospect bids fair to be second to none in the district. The Constitution has a shaft down 65 ft, with the ore body showing as strong as ever.

SHELL CREEK DISTRICT.

EL CAPITAN.—White Pine *News*, Nov. 12: The El Capitan, at Schellburn, is looking well, and good ore is being extracted. They are now hauling ore to the mill, which will be started up next Monday. A profitable run is anticipated.

SILVER CANYON DISTRICT.

ORE.—White Pine *News*, Nov. 12: At Silver canyon, Dr. Brooks' company are doing some good work in the way of dovetailing and extracting ore from the Sadie L., Blue Bello and Buckborn mines. The company's mill is also running to its full capacity.

TAYLOR DISTRICT.

MONITOR.—White Pine *News*, Nov. 12: The Monitor Co., at Taylor district are working a big boranza, and are making nice bullion shipments by every stage. No doubt, Messrs. Briggs, Lyon and McGill have one of the best mining properties in eastern Nevada, and all being practical men, they are working it to good advantage.

WARD DISTRICT.

MARTIN WHITE.—White Pine *News*, Nov. 12: The superintendent of the Martin White Co., at Ward, reports to his company that he is taking out some of the finest ore ever discovered in the mine. This, of course, means that it goes away up in the hundreds. Taken altogether, the mining interests in eastern White Pine look far more promising than for years past.

ARIZONA.

PLACERS.—Arizona *Miner*, Nov. 18: B. C. Smith, superintendent of the company that recently purchased, through Messrs. Murphy & Moody, the Jackson placers, on Lynx creek, reports that he is busily engaged clearing out the old ditch and reservoir. The ditch is over a mile and a half long, and can flume about 300 inches of water. The reservoir is on the diggings, and is used for ground sluicing. The ditch is tapped with iron pipes that are used for hydraulic mining. This property, when systematically worked, has always paid well. The late Calvin Jackson made a handsome clean-up the winter before he died. We are glad to see energetic men run this property, and will report progress from time to time.

YAVAPAI.—Doctor Farnham, who represents the Yavapai M. & M. Co., returned from a visit to some of the properties belonging to the company yesterday. He furnishes us the following particulars: On the Yavapai they have a tunnel in 200 ft, with a vein 12 ft wide, containing 6 ft of very high-grade ore. At the distance of 200 ft, the ledge is 100 ft or more beneath the surface They are now drifting south, and will soon cut the ledge to ascertain its correct width. Another property belonging to this company is the Wadleigh, containing gold, samples of which exhibited to our view were perfectly permeated with bright particles of the precious metal.

CONTACT.—Tombstone *Epitaph*, Nov. 20: The strike in the Contact is better than we were at first led to believe. It was made at a depth of 17 ft. The ore is a heavy, rich, brown and yellow carbonate. Those who have been to the mine pronounce it the most promising of anything heretofore struck in that section. We hope those having it on bond will make a fortune out of it. The millionaires who owned and bonded it rather than spend money to develop it, ought to see it prove the richest mine in this rich camp, just to make them happy for the act of generosity they performed in giving others a show to become rich men also.

WORTHINGTON (SAN DIEGO) MINING CO.—A rich strike has been made in an uprise from 130 level. A 6-inch vein of grey carbonate was encountered, assaying $200.91 silver with a trace of gold. The average of assays taken across a 4-ft ledge was $81.

COLORADO.

OLD HICKORY COPPER MINE.—Salt Lake *Tribune*, Nov. 18: Work on this mine still continues with the most encouraging results. Negotiations for one of Rankin, Brayton & Co.'s improved copper smelters have been entered into. These new copper smelters are now doing splendid work for the Copper Queen mine, Bisbee, Arizona, and have developed a good property. Other places in Arizona, California and Colorado are using these smelters and meet with unbounded success. B. A. Spear, who is their agent in Utah, expects to have, before the close of another year, quite a number of them running in Utah.

PAYROCK TUNNEL.—Cottelyou & Co., who have a lease on the HopeWell, have been at work only a little over a week, and, although they commenced in barren rock, have opened up a streak of 900 ounce ore.

BISMARCK.—The stope is still improving. A mill-run made last week contained over 230 ozs silver per ton, an increase of over 50 ozs above the preceding run. The production for the last month has paid the owners at the rate of about $11 a day for each man employed.

EAST CASHIER.—In the Italian's lease they have an average of about 6 inches of ore for about 80 ft, sometimes widening to 12 inches and sometimes pinching out to 1 inch. The last mill-run from this lease gave 601 ozs first-class and 263 ozs second class, the whole mill-run returning $2,336. This was from the work of 4 men for 6 weeks.

DUNKIRK.—Hennessy & Co., lessees, are stoping on the 420-ft level, west of the shaft, and have from 3 to 4 ft of quartz, with mineral scattered throughout the entire width. At the last mill-run, about 3 weeks since, the return was 100 ozs silver, sorted into 1 class.

MENDOTA.—For the last week the workmen have been employed in putting up a whim-house, 28x24 ft, which has delayed the work in the mine. In general the ore is improving gradually in quality, as depth is gained. The best ore, gray copper, is associated with rosin zinc and this is increasing in quantity.

PELICAN-DIVES.—Work has been stopped in the main shaft in consequence of the influx of water, but sinking will be resumed as soon as a pump can be furnished and put in place. Manager Duff has now gone east on company business and will procure the pump during his absence. Bush & Kennedy's lease is in about the same condition in every respect as we published 3 weeks since, producing about the same amount of ore. These parties have also commenced sinking on the Unicorn, 200 ft west of the main tunnel. Phillips & Co.'s lease is unchanged in character and produces the usual quality and quantity of ore. The lease of Fitzpatrick & Coughlin is looking well and improving. They have from 1 to 5 inches of high grade ore. A new lease has been let to Ed Barry and James Rowe in the old surface workings of the Pelican on the west side of Cherokee gulch. They took out about 2 tons of ore last month, carrying between 300 and 400 ozs silver.

IDAHO.

THE FIRST SMELTER CLOSED.—Wood River *Times*, Nov. 16: At 3 o'clock yesterday the Wood River Smelting Co.'s works were closed for the winter. The summer campaign of these works will mark an epoch in the history of Wood River, as the first local smelter started up. The small capacity of the furnace—10 ton per day—precluded the possibility of any larger profit accruing to the owners from its working, but by next spring they will have a 30-ton furnace, and can then look for results satisfactory in every respect.

BRODHEAD'S MINES.—Col. Brodhead, of Sawtooth, has shown us a sample of the recent strike in the Beaver Extension claim. It is a handsome specimen of black sulphuret and ruby silver ore that is evidently very rich. The sample came from the middle of Brodhead tunnel of the claim. This tunnel was started on the foot wall about a month ago. After running it a distance of 80 ft, a couple of shots were put in the ledge in the side of the tunnel, and 2½ ft of ore that will average between $300 and $400 a ton were uncovered.

THE NELLIE GROUP.—This group is composed of 6 mines situated in Smiley's gulch, and is being developed by 3 tunnels. Two of these tunnels are in the Nellie—the claim whence the group derived its name—and are just getting in the ledge. The other tunnel is in the Nellie Extension. When Col. Brodhead left this tunnel had cut into 2½ ft of ore.

MONTANA.

BELLE OF BUTTE.—*Inter-Mountain*, Nov. 18: For some time past the sinking of the Belle of Butte shaft has been vigorously progressing, and it has now attained a depth of 160 ft. Several days ago a crosscut was started south, which, yesterday, at a distance of 8 ft, struck the footwall. The ledge has since been penetrated 5 ft and the hanging wall has not yet been encountered. Mr. Jas. Talbot, from whom we obtain the above information, states that no assays have yet been made, but from the appearances of the ore, as uncovered in the crosscut, he is of excellent grade and gives promise of developing handsomely. From the footwall the crosscut, as far as extended, is all in ore, and from the rapidity with which the ledge increased in width in the upper levels, it is reasonable to assume that at the present depth an extensive ore body will be developed. In the meantime, the crosscut is being rushed ahead.

LEXINGTON.—It is not definitely settled whether or not it was the main ledge which was tapped in the Lexington on Tuesday. There is, however, no disposition to deny the fact that a large body of high-grade ore was encountered, so that in any event the strike was an important one.

ALICE.—The Bruckner furnace in the Alice mill will be fired up in a few days and will prove of vast benefit, as the stamps will operate exclusively on base ore. The bullion, too, will be finer than it is now and a considerable discount will be saved.

MORNING STAR.—We have another ore body this time. Where we passed through the ledge in the shaft, there was a pinch, but I knew the ore shoot was west, so started a drift with entire confidence. At 40 ft we struck specimens of native and wire silver, just like we had in the upper level, and then I knew that we had 'em. Yesterday morning she looked better than ever, with about 12 inches of clean, solid ore and a good deal of fine looking ledge matter. When I went down the shaft this morning, there was less ledge matter and more ore. At the distance of 50 ft from the shaft, there is now a 3-ft breast of quartz that samples 90 ozs in silver and some gold. From the upper level, at a distance of 40 ft from the shaft, we started a winze which is now 30 ft deep, and which shows in the bottom 1½ ft of very pretty ore. This will be a good deal wider when we make connection with the 200 level, and you can just imagine what a pretty piece of ground will soon be available for stoping.

PHILLIPSBURG.—Cor. *Inter-Mountain*, Nov. 18: The Hope mill is running night and day, being plentifully supplied with ore from the Hope mine, which, under the careful management of Mr. B. Ballard, the very efficient foreman of the mine, is keeping up its old time record. The Algonquin mill, which has been closed for a short time, will start up again in a few days, with plenty of ore on hand. Mr. J. K. Pardee, with his usual foresight and eye to business, has leased the Emerald mine from Messrs. Ulery & Thomas. Operations on the Trout are progressing as usual. Mr. Freeman is developing the Tintic and Cheyenne, and in all probability, we will hear from him in a short time, as this property is the extension of one of the best leads ever struck in Phillipsburg.

OREGON.

QUARTZ.—*Democratic Times*, Nov. 18: A spur of quartz has been found in the tunnel now being run to strike Geo. Schumpf's ledge near Willow Springs, and it is expected that the main ledge will be struck very soon. The prospects are announced to be favorable. George W. Lance, of the firm of Lance & Hosmer, (who are engaged in extensive mining operations on Foot's creek), was in town Wednesday after some hydraulic pipe manufactured at K. Kubli's establishment. He says that the rains furnished considerable water, but it has since run down. Charles F. Chappel & Co., of Star gulch, are at work, though with a limited supply of water. W. S. Brodbeck and Lennes Kipple are again working their claim on Dividend bar. Some of the miners have been engaged to do some work, but most of them are engaged in getting ready. Piping is going on at the mines of the Sterling Co. and Gin Liu, though the ditches are not full as yet. All the miners are getting ready for winter and a great deal of mining will be done this season, much more than last. Dan Silva, at the Grand Rapids gravel diggings, made a cleanup the other day that resulted satisfactorily. Piping still continues. Messrs. Bolt, Layton and others have purchased Hadley's interest in the great ledge recently discovered on Steamboat. The ore promises better than ever. J. W. Ingram and John Ambrose have purchased a piece of mining ground in Willow Springs precinct, and have been engaged in clearing up the ground sluice. The Squaw Lake ditch company will soon receive a large amount of new hydraulic pipe from Portland. This assures more extensive and successful operations by the company, which is all that is needed.

UTAH.

SOUTHERN UTAH PRODUCT.—Silver Reef *Miner*, Nov. 12: For the past few years Utah has held a first place among the silver-producing States and Territories of the country. And although less favored in many respects than our neighbors on the east and west, the time is fast approaching when it will lead the van in the product of the precious metal. It only remains for southern Utah to receive that recognition which is its due, and this result will soon be accomplished. San Francisco district, lying immediately on our northern boundary, within a brief time has demonstrated to the satisfaction of the most skeptical that our mineral deposits are not only large but immense. The Horn Silver is now acknowledged to be the largest developed ore body in the world, and there are many other mines in that and adjoining districts which are making a splendid record and require time and labor only to prove their worth. In our own district we can point with pride to the fact that all our mines that are being operated are paying handsome dividends, which can scarcely be said of any other within the great mineral territory. The companies that have been actively engaged for the quarter ending September 30th last—to-wit: the Christy, Stormont and Barbee & Walker with an average of 15 stamps, or 5 to the company, gave a bullion product aggregating $273,000. This will be considerably increased during the current quarter; but taking the above figures, it is safe to put the product of the stamps, allowing continuous operation, at $1,100,000 for the year ending December 31, 1881.

At the incline from the joint shaft of the Belcher and Crown Point companies repairs have been completed to a point 100 ft. below the 2560 level. They are putting their pumps in condition to handle all the water.

Practical Lectures to Mechanics.

(CONTINUED.)

Constructive Processes.

Machinery is divided into four classes:

First—Motive machinery for utilizing or converting the natural forces.

Second—Machinery for transmitting and distributing power.

Third—Machinery for applying power.

Fourth—Machinery of transportation.

Or, more briefly stated: Motive machinery; machinery of transmission; machinery of application; machinery of transportation.

Each of these classes should be treated separately, or, as we might say, some branch of either of these classes would be a sufficient theme for a lecture or a number of lectures.

The remaining part of my lecture will be devoted to

Machinery of Application,

Or, rather, to the processes performed by such machines, mainly in calling your attention to concrete facts. First, I will speak of forging:

A peculiarity of forging is that it is a kind of hand process, where the judgment must continually direct the operations, one blow determining the next, and while pieces forged may be duplicates, there is a lack of uniformity in the manner of producing them. Pieces may be shaped at a white welding heat or at a low red heat, by one or two strong blows or by a dozen lighter blows, the whole being governed by the circumstances of the work as it progresses. A smith may not throughout a whole day repeat an operation precisely in the same manner, nor can he, at the beginning of an operation, tell the length of time required to execute it, nor even the precise manner in which he will perform it. Such conditions are peculiar, and apply to forging alone.

I think proper to point out these peculiarities, not so much from any importance they may have in themselves, but to suggest critical investigation, and to dissipate any preconceived opinions of forging being a simple matter, easy to learn, and involving only commonplace operations.

Forging.

The first impressions an apprentice forms of the smith-shop as a department of an engineering establishment is that it is a black, sooty, dirty place, where a kind of rough, unskilled labor is performed—a department which does not demand much attention. How far this estimate is wrong will appear in after years, when experience has demonstrated the intricacies and difficulties of forging, and when he finds the skill in this department is more difficult to obtain, and costs more relatively than in any other. Forging as a branch of work requires, in fact, the highest skill, and is one where the operation continually depends upon the judgment of the workman, which neither power nor machines can to any extent supplant. Dirt, hard labor and heat deter men from learning to forge, and create a preference for the finishing shop, which, in most places, makes a disproportion between the number of smiths and finishers.

Forging plant consists of rolling mills, trip hammers, steam hammers, drops and punches, with furnaces, hearths and blowing apparatus for heating. A general characteristic of all forging machines is that of a great force acting throughout a short distance. Very few machines, except the largest hammers, exceed a half-inch of working range, and in average operations not one-tenth of an inch.

Percussive Force.

These conditions of short range and great force are best attained by what may be termed percussion, and by machines which act by blows instead of positive and gradual pressure; hence we find that hand and power hammers are the most common tools among those of the smith-shop.

To exert a powerful force acting through but a short distance, percussive devices are much more effective and simple than those acting by maintained or direct pressure. A hammer head may give a blow equal to many tons by its momentum, and absorb the reactive force which is equal to the blow; but if an equal force was to be exerted by screws, levers or hydraulic apparatus, we can easily see that an abutment would be required to withstand the reactive force, and that such an abutment would require a strength perhaps beyond what ingenuity could devise.

The Philosophy of Hammering.

This principle is somewhat obscure, and the nature of percussive forces not generally considered—a matter which may be illustrated by considering the action of a simple hand hammer. Few people, in witnessing the use of a hammer, or in using one themselves, ever think of it as an engine giving out tons of force, concentrating and applying power by functions which, if performed by other mechanism, would involve trains of gearing, levers or screws; and that such mechanism, if employed instead of a hammer, must lack that important function of applying force in any direction as the will and hands may direct. A simple hand hammer is in the abstract one of the most intricate of mechanical agents—that is, its action is more difficult to analyze than that of many complex machines involving trains of mechanism; yet our familiarity with hammers causes this fact to be overlooked, and the hammer has even been denied a place among those mechanical contrivances to which there has been applied the name of "mechanical powers."

Let the reader compare a hammer with a wheel and axle, inclined plane, screw or lever, as an agent for concentrating and applying power, noting the principles of its action first, and then considering its universal use, and he will conclude that, if there is a mechanical device that comprehends distinct principles, that device is the common hammer. It seems, indeed, to be one of those provisions to meet a human necessity, and without which mechanical industry could not be carried on. In the manipulation of nearly every kind of material, the hammer is continually necessary in order to exert a force beyond what the hands may do, unaided by mechanism to multiply their force. A carpenter, in driving a spike, requires a force of from one to two tons; a blacksmith requires a force of from five pounds to five tons to meet the requirements of his work; a stonemason applies a force of 100 to 1,000 lbs. in driving the edge of his tools; chipping, calking, in fact, nearly all mechanical operations consist more or less in blows, such blows being the application of accumulated force expended throughout a limited distance.

Machines and tools that operate by blows, such as hammers and drops, produce effect by the impact of a moving mass by force accumulated throughout a long range, and expending the sum of this accumulated force on an object. The reactive force not being communicated to nor resisted by the machine frames, is absorbed by the inertia of the mass which gave the blow; the machinery required in such operations being only a weight, with means to guide or direct it, and mechanism for connection with motive power. A hand hammer, for example, accumulates and applies the force of the arm, and performs all the functions of a train of mechanism, yet consists only of a block of metal and a handle to guide it.

Punches.

Machines with direct action, such as punches, shears or rolls, require first a train of mechanism of some kind to reduce the motion from the driving power so as to attain force; and secondly, this force must be balanced or resisted by strong framing, shafts and bearings. A punching machine, for example, must have framing strong enough to resist a thrust equal to the force applied to the work; hence the frames of such machines are always a huge mass, disposed in the most advantageous way to meet and resist this reactive force, while the main details of a drop machine capable of exerting an equal force consist only of a block and a pair of guides to direct its course.

Large Hammers.

Leaving out problems of mechanism in forging machines, the adaptation of pressing or percussive processes is governed mainly by the size and consequent inertia of the pieces acted upon. In order to produce a proper effect, that is, to start the particles of a piece throughout its whole depth at each blow, a certain proportion between a hammer and the piece acted upon must be maintained. For heavy forging, this principle has led to the construction of enormous hammers for the performance of such work as no pressing machinery can be made strong enough to execute, although the action of such machinery in other respects would best suit the conditions of the work. The greater share of forging processes may be performed by either blows or compression, and no doubt the latter process is the best in most cases. Yet, as before explained, machinery to act by pressure is much more complicated and expensive than hammers and drops. The tendency in practice is, however, to a more extensive employment of press-forging processes.

Crystallization.

Another peculiar feature in trip hammers is the rapidity with which crystallization takes place in the attachments for holding the die blocks to the helves, where no elastic medium can be interposed to break the concussion of the dies. Bolts to pass through the helve, although made from the most fibrous Swedish iron, will on some kinds of work not last for more than 10 days' use, and often break in a single day. The safest mode of attaching die blocks, and the one most common, is to forge them solid, with an eye or a hand to surround the end of the helve.

At the risk of laying down a proposition not warranted by science, I will mention, in connection with this matter of crystallization, that metal when disposed in the form of a ring, for some strange reason, seems to evade the influences which produce crystalline change. A hand hammer, for example, may be worn away and remain fibrous; the links of chains and the tires of wagon wheels do not become crystallized; even the tires on locomotive wheels seem to withstand this influence, although the conditions of their use are such as to promote crystallization.

Among exceptions to the ordinary plans of constructing trip hammers may be mentioned those employed in the American Armory at Springfield, U. S., where small hammers, with rigid frames and helves, the latter 30 inches long, forged from Lowmoor iron, are run at a speed of "600 blows a minute." As an example, however, they prove the necessity for elasticity, because the helves and other parts have to be often renewed, although the duty performed is very light, such as making small screws.

Connected with this matter of forging is the subject of steam hammers:

Steam Hammers.

The direct application of steam to forging hammers is without doubt the greatest improvement that has ever been made in forging machinery; not only has it simplified operations that were carried on before this invention, but has added many branches, and extended the art of forging to purposes which could never have been attained except for the steam hammer.

Keeping in view what has been said about concrete facts, let us apply the inductive process to these machines:

First—The power is connected to the hammer by means of the least possible mechanism, consisting only of a cylinder, a piston and slide valve, induction pipe and throttle valve; these few details taking the place of a steam engine, shafts, belts, cranks, springs, pulleys, gearing, in short, all such details as are required between the hammer head and the steam boiler in the case of trip hammers or crank hammers.

Second—The steam establishes the greatest possible elasticity in the connection between a hammer and the driving power, and at the same time serves to cushion the blows at both the top and bottom of the stroke, or on the top only, as occasion may require.

Third—Each blow given is an independent operation, and can be repeated at will, while in other hammers such changes can only be made throughout a series of blows by gradually increasing or diminishing their force.

Fourth—There is no direct connection between the moving parts of the hammer and the framing, except lateral guides for the hammer head; the steam being interposed as a cushion in the line of motion, this reduces the required strength and weight of the framing to a minimum, and avoids positive strains and concussion.

Fifth—The range and power of the blows, as well as the time in which they are delivered, is controlled at will; this constitutes the greatest distinction between steam and other hammers, and the particular advantage which has led to their extended use.

Sixth—Power can be transmitted to steam hammers through a small pipe, which may be carried in any direction, and for almost any distance, at a moderate expense, so that hammers may be placed in such positions as will best accommodate the work, and without reference to shafts or other machinery.

Seventh—There is no waste of power by slipping belts or other frictional contrivances to graduate motion; and finally, there is no machinery to be kept in motion when the hammer is not at work.

Elastic and Dead Blows

Steam hammers are divided into two classes, or, as we might better say, there are two modes of operating—one by dead blows and the other by elastic or rebounding blows.

This I will attempt to explain without drawings or figures. If I succeed, you will remember whatever is new in the remarks; it will not pass away like a theorem or formula might.

In operating by elastic blows, the steam piston is cushioned at both the up and down stroke, and the action of a steam hammer corresponds to that of a helve trip hammer, the steam filling the office of a vibrating spring; in this case a hammer gives a quick rebounding blow, the momentum being only in part spent upon the work, and partly arrested by cushioning on the steam in the bottom of the cylinder under the piston.

Aside from the greater rapidity with which a hammer may operate when working on this principle, there is nothing gained and much lost; and as this kind of action is imperative in any hammer that has a "maintained or positive connection" between its reciprocating parts and the valve, it is perhaps fair to infer that one reason why most automatic hammers act with elastic blows is either because of a want of knowledge as to a proper valve arrangement, or the mechanical difficulties in arranging valve gear to produce dead blows.

In working with dead blows no steam is admitted under the piston until the hammer has finished its down stroke, and expended its momentum upon the work. So different is the effect produced by these two plans of operating, that on most kinds of work a hammer of 50 lbs., working with dead blows, will perform the same duty that one of 100 lbs. will, when acting by elastic or cushioned blows.

This difference between dead and elastic strokes is so important that it has served to keep hand-moved valves in use in many cases where much could be gained by employing automatic acting hammers.

Some makers of steam hammers have so perfected the automatic class, that they may be instantly changed so as to work with either dead blows or elastic blows at pleasure, thereby combining all the advantages of both principles. This brings the steam hammer where it is hard to imagine a want of further improvement.

The valve gearing of automatic steam hammers to fill the two conditions of allowing a dead or an elastic blow, furnishes one of the most interesting examples of mechanical combination.

It was stated that to give a dead or stamp stroke, the valve must move and admit steam beneath the piston after the hammer has made a blow and stopped on the work, and that such a movement of the valve could not be imparted by any maintained connection between the hammer head and valve. This problem is met by connecting the drop or hammer head with some mechanism which will, by reason of its momentum, continue to "move after the hammer head stops." This mechanism may consist of various devices. Messrs. Massey, in England, and Messrs. Ferris & Miles in America, employ a swinging wiper bar, which is, by reason of its weight or inertia, retarded, and does not follow the hammer head closely on the down stroke, but swings into contact and opens the valve after the hammer has come to a full stop.

By holding this wiper bar continuously in contact with the hammer drop, elastic or rebounding blows are given, and by adding weight in certain positions to the wiper bar, its motion is so retarded that a hammer will act as a stamp or drop. A German firm employs the concussion of the blow to disengage valve gear, so that it may fall and effect this after movement of the valves. Other engineers effect the same end by employing the momentum of the valve itself, having it connected to the drop by a slotted or yielding connection, which allows an independent movement of the valve after the hammer stops.

There is a kind of hammers not known in this country, or not employed at least, that may be called compound hammers.

Compound Hammers.

Another principle to be noticed in connection with hammers and forging processes is that of the inertia of the piece operated upon—a matter of no little importance in the heavier kinds of work.

When a piece is placed on an anvil, and struck on the top side with a certain force, the bottom or anvil side of the piece does not receive an equal force. A share of the blow is absorbed by the inertia of the piece struck, and the effect on the bottom side is, theoretically, as the force of the blow, less the cushioning effect and the inertia of the pieces acted upon.

In practice this difference of effect on the top and bottom, or between the anvil and hammer sides of a piece, is much greater than would be supposed. The yielding of the soft metal on the top cushions the blow and protects the under side from the force. The effect produced by a blow struck upon hot iron cannot be estimated by the force of the blow; it requires, to use a technical term, a certain amount of force to "start" the iron, and anything less than this force has but little effect in moving the particles and changing the form of a piece.

From this it may be seen that there must occur a great loss of power in operating on large pieces, for whatever force is absorbed by inertia has no effect on the under side. By watching a smith using a hand-hammer, it will be seen that whenever a piece operated upon is heavier than the hammer employed, but little, if any effect is produced on the anvil or bottom surface, nor is this loss of effect the only one. The expense of heating, which generally exceeds that of shaping forgings, is directly as the amount of shaping that may be done at each heat; and consequently, if the two sides of a piece, instead of one, can be equally acted upon, one-half the the heating will be saved.

Another object gained by equal action on both sides of large pieces is the quality of the forgings produced, which is generally improved by the rapidity of the shaping processes, and injured by too frequent heating.

The loss of effect by the inertia of the pieces acted upon increases with the weight of the work; not only the loss of the power, but also the expense of heating increases with the size of the pieces. There is, however, such a difference in the mechanical conditions between light and heavy forging, that for any but a heavy class of work there would be more lost than gained in attempting to operate on both sides of pieces at the same time.

To attain a double effect, and avoid the loss pointed out, Mr. Ramsbottom designed what may be called compound hammers, consisting of two independent heads or rams moving in opposite directions, and acting simultaneously upon pieces held between them.

It would be inferred that the arrangement of these double-acting hammers must necessarily be complicated and expensive, but the contrary is the fact. The rams are simply two masses of iron mounted on wheels that run on ways, like a truck, and the impact of the hammers, so far as not absorbed in the work, is neutralized by each other. No shock or jar is communicated to framing or foundations as in the case of single-acting hammers that have fixed anvils. The same rule applies in the back stroke of the hammers, as the links which move them are connected together at the center, where the power is applied at right angles to the line of the hammer movement. The links connecting the two hammers constitute, in effect, a toggle joint, the steam piston being attached where they meet in the center.

The steam cylinder which moves the hammers is set in the earth at some depth below the plane upon which they move, and even when the heaviest work is done there is no perceptible jar when one is standing near the hammers, as there always is with those which have a vertical movement and are single acting.

I will next refer to machine combination, or combined machines as we generally say. The connection between this subject and forging is not very apparent; indeed is wanting, because I believe steam and trip hammers to be almost the only machines that have not been combined with something else. The reason is, no doubt, that hammers will shake off almost any kind of attachment, even their own parts.

Machine Combination.

The reasons that favor combination of functions in machines, and the effects that such combinations may produce, are so various that the problem has led to a great diversity of opinions and practice among both those who construct, and even those who employ machines. It may be said, too, that a great share of the

combinations found in machines, such as those to turn, mill, bore, slot and drill in iron fitting, are not due to any deliberate plan on the part of the makers, so much as to an opinion that such machines represent a double or increased capacity. So far has combination in machines been carried, that in one case that came under the writer's notice, a machine was arranged to perform nearly every operation required in finishing the parts of machinery; completely organized, and displaying a high order of mechanical ability in design and arrangement, but practically of no more value than a single machine tool, because but one operation at a time could be performed.

First—By combining two or more operations in one machine, the only objects gained are a slight saving in first cost, one frame answering for two or more machines, and a saving of floor room.

Second—In a machine where two or more operations are combined, the capacity of such a machine is only as a single one of these operations, unless more than one can be carried on at the same time without interfering one with another.

Third—Combination machines can only be employed with success when one attendant performs all the operations, and when the change from one to another requires but little adjustment and re-arrangement.

Fourth—The arrangement of the parts of a combination machine have to be modified by the relations between them, instead of being adapted directly to the work to be performed.

Fifth—The cost of special adaptation, and the usual inconvenience of fitting combination machines when their parts operate independently, often equals and sometimes exceeds what is saved in framing and floor space.

Referring first to the saving effected by combining several operations in one machine, there is perhaps not one constructor in 20 that ever stops to consider what is really gained, and perhaps not one purchaser in a hundred that does the same thing. The impression is that when one machine performs two operations it saves a second machine. A remarkable example of this exists in the manufacture of combination machines in Europe for working wood, where it is common to find complicated machines that will perform all the operations of a joiner's shop, but as a rule only one thing at a time, and usually in an inconvenient manner, each operation being hampered and interfered with by another; and in changing from one kind of work to another, the adjustments and changes generally equal and sometimes exceed the work to be done. What is stranger still, is that such machines are purchased, when their cost often equals that of separate machines to perform the same work.

In metal working, owing to a more perfect division of labor, and a more intelligent manipulation than in wood-working, there is less combination in machines—in fact, a combination machine for metal work is rarely seen at this day, and never under circumstances where it occasions actual loss. The advantage of combination, as said, can only be in the framing and floor space occupied by the machines, but these considerations, to be estimated by a proper standard, are quite insignificant when compared with other items in the cost of machine operating, such as the attendance, interest on the invested cost of the machine, depreciation of value by wear, repairing and so on.

Assuming, for example, that a machine will cost as much as the wages of an attendant for one year, which is not far from an average estimate for iron-working machine tools, and that interest, wear and repairs amount to 10% on this sum, then the attendance would cost 10 times as much as the machine; in other words, the wages paid to a workman to attend a machine is on an average 10 times as much as the other expenses attending its operation, power excepted. This assumed, it follows that in machine tools any improvement directed to labor saving is worth *10 times* as much as an equal improvement directed to the economy of first cost.

This mode of reasoning will lead to proper estimates of the difference in value between good tools and inferior tools; the results of performance instead of the investment being first considered, because the expenses of operating are, as before assumed, usually 10 times as great as the interest on the value of a machine.

In view of these propositions, I need hardly say to what object machine improvements should be directed, nor which of the considerations named are most affected by a combination of machine functions. The fact is that if estimates could be prepared, showing the actual effect of machine combinations, it would astonish those who have not investigated the matter, and in many cases show a loss of the whole cost of such machines each year. The effect of combination machines is, however, by no means uniform. The remarks made apply to standard machines employed in the regular work of an engineering or other establishment. In exceptional cases it may be expedient to use combined machines. In the tool-room of machine shops, for instance, where one man can usually perform the main part of the work, and where there is but little space for machines, the conditions are especially favorable to combination machines, such as may be used in milling, turning, drilling and so on; but wherever there is a necessity or an opportunity to carry on two or more of these operations at the same time, the cost of separate machines is but a small consideration when compared with the saving of labor that may be effected by independent tools to perform each operation. The tendency of manufacturing processes of every kind at this time, is to a division of labor, and to a separation of each operation into as many branches as possible, so that study spent in "segregating" instead of "aggregating" machine functions is most likely to produce profitable results.

A great share of the alleged improvements in machinery, when investigated, will be found to consist in nothing more than the combination of several functions in one machine, the novelty of the arrangement leading to an impression of utility and increased effect.

Useful Information.

The "Eastlake Style" of Architecture.

This modern idea of architecture is of comparatively recent origin, being the outgrowth of conceptions originating with Mr. Charles E. Eastlake of England—not as a style of house architecture, but in connection with house furniture and internal decorations, as contained in a published work by Mr. Eastlake, entitled "Hints on Household Taste." Its peculiar features, however, soon became popular, not only in the sphere of the mechanical arts to which it was first applied, but in the external embellishment of buildings. This popularity, to a greater or less extent, has spread throughout all sections of the United States, and is now being greatly sought after upon the Pacific coast.

Unfortunately, it is simply a "style"—not a classified "order" of architecture, with defined principles of treatment, and rules of application and delineation. It is so unrestrained in its requirements, that the wildest caoeeits of the uneducated pretender may be imposed, and the most absurd and distorted features defended as "in keeping with the style." Delineated with accurate taste and good judgment, its application in the construction of a certain class of buildings may be made pleasing to the eye; but the excessive *gaucherie* indulged in by a class of reckless adventurers, who abuse the integrity of this new idea by extravagant, unsightly and ill-conceived creations of their own, is calculated to render it offensive and repulsive to those enjoying a fair degree of refinement in the æsthetics of architecture; this may cause its rejection even as a "style," except by a limited number who prefer oddities and peculiar things because they are such.

Could Charles E. Eastlake behold some of the extravagant delineations covered by his name, he would doubtless cry to the gods to blot out the monstrosities as hideous deformities. Judicious liberties and combinations are excusable in all orders and styles of architecture; but when they run rampant, with no regard to consistency, beauty or harmony, the doctrine and rules of propriety cease, and disorder and distraction ensue. The tendency of the "new style" runs in this direction, as it provides the basis upon which unqualified men may operate, and find a defense for their stupid creations.

"All can't invent and imitate,
No more than those who clothe us can create."

And so it runs with the Eastlake style. Those who can invent nothing meritorious in architecture can imitate the new idea; that is to say they can scribble up something that *looks peculiar*, and give it the name of Eastlake.—*California Architect.*

Bismuth in Soft Solders.—The fusibility of soft solders is increased by adding bismuth to the composition. An alloy of lead four parts, tin four parts, and bismuth one part is easily melted; but this alloy may itself be soldered with an alloy of lead two parts, bismuth two parts, and tin one part. By adding mercury a still more fusible solder can be made. Equal parts of lead, bismuth, and mercury, with two parts of tin, will make a composition which melts at 122° F., or an alloy of tin five parts, lead three parts, and bismuth three parts will melt in boiling water. In mixing these solders, melt the least fusible metal first in an iron ladle, then add the others in accordance with their infusibility. To cast stripe of solder, pour the molten metal on a flat surface of stone or metal.

Compressed Fuel From Coal Dust.—An interesting process for preparing compressed fuel from coal dust has been devised by Mr. L. Trallo. The dust is placed in an iron vessel provided with an archimedean screw and heated by means of steam. As the vapor is driven out of the dust, it is withdrawn from the apparatus by a large air pump, and at the same time a certain distillation of the volatile portions of the coal takes place, which renders it somewhat cohesive. It is then pressed into bricks of a suitable size by means of a steam ram. The fuel thus prepared is said to give general satisfaction in Germany, where the process is quite extensively used. A detailed description of the process of the mechanical welding together of various solids, will be found under the head of "Mechanical Progress" in this issue of the Press.

Improvement in Silk Winding.—An improvement in machines for winding silk has been patented by Mr. Henry H. Bartlett, of Watertown, Conn. The object of the invention is to soften raw silk and prevent generation of electricity in boiled silk during the process of winding. The invention consists in providing the winding machine with a steam generator for dampening or moistening the silk by a spray of steam, whereby the gum on the raw silk is kept soft, and in case of boiled silk it is rendered flexible while being wound, and the generation of electricity is prevented. The steam generator for effecting these results is arranged below the swifts of the machine, and is provided with perforations in its upper side for the distribution of steam to the silk on the swifts.

The Blue Color of Milk.—Herr Hansse, an authority in such matters, explains in a recent foreign scientific journal, the cause of the blue color in milk. He has discovered in milk which has become blue, a peculiar microscopical organism, known as *bacteria*, which multiplies with very great rapidity, and in so doing produces a peculiar blue matter similar to aniline. Milk which is kept in such a manner as to prevent the access of these organisms does not become blue. In view of these facts, it is evident that blue milk is unfit for food; and, although it may be eaten with apparent impunity by adults with vigorous digestive powers, it should never be given to children, whose weaker stomachs would be unable to resist the tendency to decomposition which such milk possesses.

Poisonous Honey.—In bad seasons honey in some localities is apt to be poisonous. This arises from the fact that in such seasons the bees are often obliged to gather it from poisonous flowers. Great care should be taken to remove all poisonous plants from the neighborhood of hives. In 1790 a great many people in Philadelphia died from eating honey gathered from the flowers of the kalmia latifolia. In good seasons the bees avoid poisonous plants.

The Vineyard.

Lemons for Cancer.

Written for the Press by Laura J. Dakin.

I knew Mr StC. when I lived in Massachusetts. He had a cancer on his right hand, and a terrible looking hand it was—as thick as four common hands. The cancer at the commencement resembled a wart, and they called it a cancerous wart. He had employed several physicians who tried everything they knew. Nitrate of silver was among the remedies prescribed; but nothing seemed to be of any avail. He was finally persuaded to go to the hospital, where they were supposed to have doctors who ought to fully understand his case. But he hated to go, he was getting quite old, and felt as though going to the hospital meant being shut up away from all his friends. Yet his hand was such a torture to him he consented at last to go. His daughter went over to the hospital with him and the doctors got about him and looked at his hand. One wanted him in charge, and another wanted him; and a third thought he could do best by him. There seemed to be a hint at amputation, and the poor old man got frightened and begged his daughter to let him go home and have his liberty. So home they went, and that evening his grandson was reading aloud from a newspaper and came across this one line: "Cure for a cancer: Lemon poultice."

"Why not try it for grandpa?" said the boy.

"It couldn't do any harm," replied his mother; "I think we will. Put on your cap and run down to the grocers and get a dozen lemons."

The lemons were soon brought, and the question was, how to prepare the poultice. As there were no directions she did the best she knew how—took two or three lemons, squeezed out the insides, removed the seeds and stirred in pounded crackers to thicken it. I think she warmed it so as to soften the cracker, and then applied it to the hand. Well, for three hours that man walked the floor in such agony as he never suffered before. But he would not have the poultice removed, and, at the end of three hours, the pain began to lessen. In the morning that poultice was taken off and a fresh one applied, which he kept on 24 hours. In trying to remove the fourth poultice it stuck so to his hand the daughter feared hurting him when she tried to remove it.

"Never mind," said Mr. StC., "just pull it off anyhow."

So she gave a steady pull, and out came the whole cancer, leaving a hole so large she could have set a coffee cup into it. The cancer was as black as ink; that might have been caused by the nitrate of silver which had been used.

The hand began to heal right away, and in a few months was so well he could work as hard as other men of his age. He cut and split cord wood for my husband that winter, and that, you know, is pretty hard on the hands.

I have written the above story of Mr. StC.'s case very nearly as I lately heard it from a friend, hoping it might lead some sufferer to try the "lemon poultice remedy" for themselves, as I know many give up in despair when they find they are afflicted by that dreaded scourge—cancer.

I knew another case, that of an editor in Vermont, who had what was said to be a cancer commence in his cheek. He immediately changed his diet to bread and milk and vegetables, avoiding meat and all pastry. Instead of getting larger the sore gradually decreased in size till it disappeared.

I have read a well authenticated account of a lady who had a cancer as large as a pullet's egg, who spread raw, mashed cranberries on a cloth and applied as a poultice, changing it three times a day, until the whole was drawn away—the cancer becoming softened and decreasing in size until completely cured.

"A jeweler had a cancerous pimple on his cheek, in using gold dissolved in nitro-muriatic acid he unconsciously rubbed the cancer with his impregnated fingers, and was surprised to find it speedily change appearance and shortly after disappear. Proportions one ounce acid to six ounces chloride of gold." This remedy might be used where poultices could not be applied. I copy it and the one before it, from an article in the *Toledo Blade*.

[The cases referred to by our correspondent were undoubtedly cancerous tumors and not true cancers. Among the tumors admitted by general consent into the order of cancers there are widely diffsrent degrees of malignity, the most malignant of which—the true cancer—seldom, if ever, yields to any other treatment than the knife, and then only when it is taken early, before it invades the lymphatic glands.

The practical distinction of these tumors involves the closest observations and a thorough knowledge of the anatomy and relations of the textures in which they arise, including also an intimate acquaintance with the minute structure of such growths, such as can only be obtained by a skillful use of the microscope.

There are many species of cancerous tumors which readily yield to simple treatment, and it is such cases generally which are largely talked about and advertised by quacks as wondrous cures. It is best in all cases of suspected cancer to apply to a well educated physician. If it should prove a simple tumor he will treat it better than any self-advertised "cancer doctor," and for less money. If it should prove a true cancer, you will always be the safer in such hands. A "quack" never yet healed a true cancer; and they never advertise their failures. Eds. Press.]

Is Dying Painful?

Our own observation fully accords with the opinion expressed by a physician, that in all ordinary cases there is little physical pain in dying. A previous correspondent has said that, "as a physical fact, in 99 cases out of 100 the act of death is suffering and agony which only those familiar with it can understand." To which the physician replies:

"I beg leave, as a physician, to object very decidedly to this statement. Since I began my novitiate on the battle fields of the South, I had been a frequent observer of the passing out of my fellow-beings, in army and navy, in large hospitals—civil and military, and in private life, and hence cannot help feeling that what I have seen must be a fair sample of the methods of dying peculiar to our race.

"The result of these sad observations, covering 18 years, is that the vast majority of persons do not find death 'suffering and agony.' Many suffer from the various illnesses from which they recover than most do in the article of death. A very large proportion become unconscious, and hence pass away without distress to themselves; while as regards those who retain a good measure of intelligence before life is extinct, I have been considerably surprised, considering my early religious teaching, to discern in them an almost general indifference to their fate.

"I have always supposed that, in spite of apparent mental lucidity, disease clouded the intellect so that apathy becomes the ordinary state of the dying. Of the few deaths I have witnessed, the mere onlookers might call horrible, there was good reason to believe the patient unconscious."—*New York Observer.*

Sleep and Sleeplessness.—Dr. J. M. Granville, in an interesting work on this subject, says, with reference to the difficulty some persons find in getting to sleep: "Habit greatly helps the performance of the initial act, and the cultivation of a habit of going to sleep in a particular way, at a particular time, will do more to procure regular and healthy sleep than any other artifice. The formation of the habit is, in fact, the creation or development of a special center or combination in the nervous system, which will henceforward produce sleep as a natural rhythmical process. If this were more generally recognized, persons from sleeplessness of the sort which consists simply in being unable to go to sleep, would set themselves resolutely to form such a habit. It is necessary that the training should be explicit, and include attention to details. It is not very important what a person does with this intention of going to sleep, but he should do precisely the same thing, in the same way, at the same time, and under as nearly as possible the same conditions, night after night, for a considerable period, say three or four weeks."

The Roseberg (Oregon) Land Office sold during October, 413 acres of land for cash, admitter 24 homestead entries, covering 3,259 acres, and 21 preemption fillings, besides timber entries etc.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Construction of Geological Cross Sections; Working Mines on Lease; The Gold Run Suit, 345. Passing Events; Working Deep Gold Mines; Nevada Bullion; Lectures to Mechanics; Portable Drilling Machines; Thanksgiving, 352. Notices of Recent Patents, 356.

ILLUSTRATIONS.—Construction of Geological Cross Sections, 345. Morgan's Feathering Paddle, 353.

CORRESPONDENCE.—The Revolution, 346.

MISCELLANEOUS.—Silver Canyon; "Float" Miners; A New Mining Ditch; The Prospects at Tombstone; Hite's Cove District; Concentrations, 346.

MECHANICAL PROGRESS.—Painting of Cement and Plaster; The "London" Gas Engine; Brain Power and Machine Work; Resistance of Steel to Fracture; To Detect a Flaw in Iron; The Bursting of Saws; A New Wrist Pin Oiler; Fine Drilling; Treatment of New Files; Iron Railway Sleepers, 347.

SCIENTIFIC PROGRESS.—Molecular Attraction; The Nature of Coal; The Cycle of the Seasons; The Light of the Stars; Climate and Altitude; Preventing Water from Freezing in Hydraulic Apparatus; An Observatory for Boston, 347.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meeting and Dividends, 348.

MINING SUMMARY from the various counties of California, Montana, Nevada, Colorado, Utah, Oregon, Idaho, 348-49.

USEFUL INFORMATION.—The "Eastlake Style" of Architecture; Bismuth in Soft Solders; Compressed Fuel from Coal Dust; Improvement in Silk Winding; The Blue Color of Milk; Poisonous Honey, 351

GOOD HEALTH.—Lemons for Cancer; Is Dying Painful? Sleep and Sleeplessness, 351.

Business Announcements.

Framing Machine—Golden State & Miners' Iron Works.
Knight Water Wheel—Almarian B. Paul, Agent, S. F.

Passing Events.

This week is a broken one, onr annual set day for Thanksgiving coming in the middle of it. California has for this year, anyhow, great canse to celebrate the day, as it is now in an era of prosperity which hae been wanting for some time. Our only drawback is the nnfortunate controversy about the debris question. Mint Director Burchard, in his lately issued report upon the production of precions metals, estimates that the annnal output of gold in California during the next 10 years will he $15,000,000. He shows that of this amount the hydraulic mines will produce $10,000,000 per year if they are permitted to continue in operation. As we can not afford to lose ten millions, it is to he hoped the compromise will he arranged.

In this number of the Press we give two lectures on mechanical snbjects, hoth by workers in our midst. These are specially valuable to our mechanical readers.

From the mining regione the news is generally encouraging, except from the Comstock. At that center no bonanzas are announced, though that is where they are most anxiously looked for.

Excitement at Deep Creek.—We learn that there is quite a mining excitement at Deep creek, on the Utah line. Many claims have heen located there recently, and it is said that Salt Lake parties are becoming interested in many of the mines. A hoom is looked for ont that way in the spring.

But for the Indians, there would have been a large influx of people to Arizona and New Mexico this winter, eeeking investments. As it ie now, much of that capital will find employment in Mexico, especially Sonora, in which conntry there ie at present much interest.

Deep Gold Mining.

Tbe Australians seem to be going through an experience which may bs of benefit to us in California bsfore long. In soms of ths older gold districts in the colonies, as dspth was reached mining langnished. Then in several places they went to work with diamond drills, and by proving the ground qnickly and easily, have given a new impetns and inspired greatsr confidencs by proving the permanence of ths lodee at greater depth.

A recent report from there ehows that in the Crown Cross United mine at Stawell the diamond drill was set to work at a depth of 1,322 ft., and on boring 375 ft. further had pierced a recf of about 10 ft. in thicknss. The core has been tested, and is found to contain gold at the rate of 17 dwts. 3 grs. per ton, a prospect with which the company is eo satisfied that it proposes at once to sink for the reef. This work will occupy a year, and will cost about 4,000*l*. The discovery is entirely due to the valuable instrument of which miners have recently secured the use. Without it it is quite possible that the company would never have incnrred the expenditure necessary to sink a ehaft. This is not the only, thongh it is the most prominent, instance of the usefulnss of the drill as an instrument for prospecting. It is not long eince that its use in a claim at Hepburn led to discoveries which improved the quotable nature of the claim to the extent of 10,000*l*. At Stawell, we learn that the discovery in the Crown Cross United mine of a paying reef at a depth of 1,700 ft. has infused a new spirit of enterprise into mining work. The discovery in itself of paying quartz at this great depth is of vast importance as giving an enormons extension to tbe area of the known workable ground, and it immensely enlargee viewe of the permanence of gold mining in the colony. But the great point of interest is that the discovery was made by means of an instrument which reduces the cost of undergrond exploration in a great degree. It is quite natural that the utility of the instrnment should epecially strike the pnblic mind when it leads to a positive discovery. But it is easy to see that it is equally useful when its use indicates at a small outlay the inutility of expending money in any certain direction.

It is represented that the discovery of the Smeaton and Kingston gold fielde was due to diamond drille which seem to be finding great favor in the colonies. Gympie (Qneensland) is turning ont splendid returns from the new finds at the deeper levels, and one mine which was offered at 500*l*. within the last 18 months is now worth 150,000*l*., and 120,000*l*. casb was refused last month for it.

Here in California many people are prejudiced againet the diamond drill on account of the way it has been used in Nevada silver mining in times past, the "insiders" baing able by means of it to hold the key to the situation. It has proven itself so very useful, however, of late years that the wonder is the drill is not more frequently used in prospecting in gold mining regions. The conclusions reached in the work in Australia with reference to the gold ore at great depthe will encourage many persons here.

Nevada Bullion.

According to the statement of the Connty Recorder of Storey conty, the bullion yield of the Comstock mines for the qnarter ending September 30th, was as follows: Total tons of ore and tallinge, 29,862 and 1,462 lbs. Total gross yield, $251,495.99. Total net yield, $44,228 97. Total tax, $1,822.48. Average grosa valne of ore per ton, 14.47. Net yield of ore per ton, $2.87. Average tax on ore per ton, about 12 cents. Average gross valne of tailings per ton, $4.37. Net yield of tailings per ton, 55 cents nearly. Average tax per ton on tailings, 2 134 1,000 cents. A comparison of the returns for the last two quarters gives the following results: Decrease in ore extracted dnring the last quarter, 9,780 tons. Decrease in gross value of ore. $199-269,28. Decrease in net yield of ore, $39,732.17. Decrease of tax on ore, $1,897.24. Increase in tailings redneed dnring the last quarter, 13,253 tons. Increase in grose value of tailings, $55,-602.62. Increase in net yield of tailings, $7,-538.78. Increase in tax on tailings, $285.44. Total decrease in tax on the net proceeds of ore and tallinge extracted and reduced for the past qnarter over that ending Jnne 30th, $1,611.80.

A stampede is in progress toward Beni river, in Bolivia, nnexplored nntil last winter, when E. A. Heath ascended it and discovered vast forests of cinchona and cacutchne. Ten thousand men have gone there, and the export of rubber has risen from 15,000 to 75,000 lbs., with promises of 6,000,000 next year. Dr. Heath ie sanguine of finding rich deposits of the precious metals and medicinal plants along the Madre de Dios.

Says the Bodie *Free Press;* "It has besn well observed that as operations become more centralized and general, co-operations will entcr into the future work and plans of mining. Isolated mining companies have been compelled to erect machinery for treating their ores, and many disasters have been the result. One shaft, pump, hoisting works of large capacity will do the work of a number of smaller ones, cheaper and better."

Lectures to Mechanics.

We give in tbis issne of the Mining and Scientific Press, full reports of lectures delivered to the mechanics of San Francisco by John Richards, of the S. F. Tool Co. and G. W. Dickis, of ths Risdon Iron Works. Both of these lectures are by practical men on their specialties, and are worthy of careful perusal by all psrsons interested in mechanics.

We are of the opinion that tbe single course of lectures of which these form a part will call the attention of the citizsns of this city to the great need of a regular course of snch lectures to be given each winter to the yonng people of the town. There are plenty of gentlemen who could be found to give a portion of their time to such a purpose provided they can see any practical results are likely to follow. When the lectures are given in plain, simple language, and not so scientific as to be beyond the reach of an ordlnary mechanic, they are mucb more nsefnl than when too "deep." And they must be given in a place where mechanics will be likely to go. Big halle, with committees, and parade and show, gather a lot of people who want to advertise themselves, but do not gather the right kind of hearere. The lectnres now being delivered, have been so far just what was wanted.

Portable Drilling Machines.

For the pnrpose of producing a portable self-acting adjustable feed drilling machine that can he readily adapted and clamped to heavy pieces of machinery or iron bridge work, for the purpose of drilling or boring holes in the same, at a speed proportionate to the hole to he drilled, an ingenious arrangement is proposed hy Messrs. Lees, of Hollinwood, Manchester. A euitable frame supports the drill spindle and accompanying driving apparatns, which are secured to a horizontal arm, which arm, when required, will revolve so ae to point the drlll spindle to almost any angle. The revolvlng motion of the drill spindle is obtained hy the application of a handle or pulley and a pair of ordinary bevel wheels, one of which is fixed to the handle or pulley and the other to the drill spindle. The stud carrying the handle or pulley and its bevel wheel may, with equal convenience, occupy their several positions in order to facilitate the drilling of the work at difficult angles. The self-feed of the drill spindle is effected hy the application of four small differential spar wheels fixed above the bevel wheel on the drill spindle, two of whicb revolve with, and are on, the drill spindle, and the remaining two differential wheels are on a stud parallel to it, which, with the wheels keyed on it, is lifted when the drill is to be put out of gear. The lifting of the stud and the two wheels thereon enables the operator to put the tool quickly to or withdraw it speedily from its work.

Thanksgiving.

We did not need the proclamation of a Governor and a President to make the people of California give a day this week to thanksgiving. There is need enough for rejoicing in our improved prospects, onr present prosperity and our rsnewed vigor and enterprise.

True, jnst at present California mining interests are to some extent under a clond owing to the unfortunate debris contest; but aside from this everything is harmonious. Our mechanical progress is very rapid. All onr fonndries are filled with work; new industries are springing up on every hand. It is gratifying to one who has full faith in prodnctive effort as the only true basis of prosperity, to see that the whole population are looking no more for a "lively stock market" to advance their trade and manfacturing interests, but are with one accord attributing the present general activity to the downfall of the power they once courted. It is a signal triumph for industry. It alone wonld give occasion for a general thanksgiving.

The theme is one which thie week commends itself to many; and we do not therefore devote much space to it. Nevertheless, we, in common with others, feel like congratulating onrselves that on this occasion particnlarly, we can enter into the joys of thanksgiving with a full sense that we have a great deal to be thankful for.

The Garfield Shaft.—In the last issue of the Press we described the natnre of the machinery which is to be built for the new Garfield ehaft, at the New Almaden mine, Santa Clara county. Instead of the rope there described, after consultation with experienced mining men, it is thought best to nse flat crucible steel wire rope 3½ inches wide by ⅜ thick, of which the working load is 12,000 pounds and the weight per 100 feet, 242 pounds. Shaft will have one compartment for hoisting, one for pnmps. Two reels will be reqnired, one carrying a tail rope in pnmp compartment as a counter balance.

The Mt. Pleasant mine, near Grizzly flat, El Dorado county, has a new 20-stamp mill, with all modern improvements, a set of hoisting works, etc. It now belongs to Eastern parties.

Marine Engineering on the Pacific Coast.

The following lecture was delivered at Capt. McNevin's nautical school on Thursday evening of last week by G. W. Dickie, of the Risdon Iron Works:

Aftsr consenting to taks part in this course of lectures, I felt some difficulty in choosing a subject npon which I could talk to you in an intsligent way, and one in which yon would feel interested. Taking it for granted that the most of my hearers to-night are connected with mechanical pursnits, and that you are hsre expecting to learn something that will be of nse to you in pursnit of your daily calling, I felt that my subject must not only treat of some branch of mechanical engineering, but that I must endeavor to point out how *you*, who are to help in its future development, can best prepare yourselves to take part in advancing that branch of our honorable calling that I have chosen for my subject to-night, namely—"Marine Engineering on the Pacific Coast." The greater part of my work here during the past 10 years has been devoted to this branch of engineering; and while circumstances have compelled me to study up and execute important works in other branches, I have always considered that the marine engine was my special etudy, and I trust that the day is not far off when it will be *here* (as it is in the older conntriee) considered enough if a man is proficient in one branch of his profession. My advice to the young men who hear me to-night, and who may have large ideas as to the extent of the field they will be able to cultivate in machanics, is to try a little patch first.

Our First Knowledge

Is so apt to lift us up, that we think our vision can grasp the whole mechanical field; the beginner is generally more satisfied with his progress than he who has long been in the work. Those thinge in mechanics, which, to the beginner, like the stem of a tree, seem simple and easily grasped, spread away heneath into interminable roots, where we can never count them all, nor reach the end of any one. Just try to master a single subject, and you will find it so. The road becomee longer and the field wider as you proceed; side pathe strike off; related sciences penetrate yonr special subject of etudy, which must be known if you are to understand your own department thoronghly, till yon feel how brief is life, and how long is knowledge. The more one knows and the longer one works, the more he feels it, and the wider the application of mechanical science growe as a whole, the less is the portion that can he overtaken hy each individual. Each mind works like a glow-worm, with its little spot of light around it, hut there is no one broad enough to pour illumination on the whole.

This branch of engineering that we are to consider to-night will, in the future, he the most important one on this coast. It will give more positions of trust than any other to the young engineers who are preparing to make their presence felt among us, and it is to those young men whom we expect by-and-by to

Design and to Handle Our Steamship Engines,

That I wish more especially to address myself to-night. I do not expect to he able to tell you much that is new; in fact, I have no desire to do so. My aim will be to point out the direction in which you are to push your inquiries. We will therefore consider marine engineering on the Pacific coast: First, with reference to design—the drawing-room; second, construction—the ship; and third, management—on board ship. There is perhaps no richer field for the clever designer to labor in than that of

Designing Marine Engines.

Every vessel he is called upon to provide engines for, needs special treatment; in fact, the vessel throughout, hoth hull and machinery, should he a homogeneous design. Yonr design ehould be in harmony with its surroundings; in fact, it shonld be *such*, that an engineer of taste, boarding the vessel you have engined, should find just what he expected in the engine-room of euch a vassel. It is this feature of harmony in design that makes the donhle-ended boilers and those heautifully deeigned three-cylinder engines of Mr. Kirk's so appropriate when worked into the lnngitudinal section of a vessel of great length in proportion to depth and breadth.

Not only should your engine, in form and type, conform to the main fixtures of the vessel it is to propel, hut in finish it ehould harmonize with the general finish and appointments with which it is surrounded.

Another point to he observed in general deeigning, and which I will advert to now, before enteriog into details, is this:

Make Provision for Light

In your engine and fire-rooms. Here yon will encounter your first and most determined opposition of the ship owner, or, more properly speaking, his superintending captain. I am most decidedly of the opinion that many steamship disasters and much rapid deterioration is induced by darkness in the engine-rooms and fire-rooms of many otherwise well-appointed vessels. Dirt accumulatee in dark places, where It would not be allowed if there were light to make it visible; proper inspection would he had of parts that no inspecting eye ever sees hecanse of the darkness and dirt. Make your design with ample provision for light, and fight for deck room to obtain it. Remember that yon will have to compromise and plan to do with less than you call for in yonr design; therefore

begin large enough to be able to make concession for peace.

We will now consider the leading types of marine engines for ocean service, and for two reasons we will first take paddle, or, as you term them,

Side-Wheel Engines.

First, because of their age and respectability; and second, because I believe there is a future for this class of engine on the Pacific coast. In America, there is but one type of paddle engine in general use at present, and for large radial wheels, turning slowly and yet attaining considerable piston speed, the American beam engine has had a long and honorable term of office, and for certain purposes should still be retained. But if a fast ocean passenger service should be required on this coast, as it will be when our coast population increases, then long, low saloon steamers will be built, maybe of California steel, with fast-running feathering-wheels. I have advocated such vessels for some years past, and I doubt not but some of you will take part in the building of them before many years have gone by.

In that class of engines where the cylinders are placed directly under the shaft, I would give the first place to

The Oscillating Engine.

This class of engine was first built by Henry Mendely for the Thames river steamers about 1822 or 1824. His son, Joseph, was the first to construct oscillating engines with slide valves worked by eccentrics, about the year 1827. This arrangement of valve gear came so perfect from his hands that no attempt has been made to improve upon it. The engines of Her British Majesty's yacht, *Osborne*, are, I think, the largest pair of oscillating engines in use. They were built by Mandely & Sons in 1870. The cylinders are 100 inches in diameter and 8-ft. stroke, and make 32 revolutions, indicating 3,374 horse power. There are at present some fine specimens of compound oscillating engines being built by Mandely for continental boats of the London, Chatham and Dover railway. Having in view the advantage of a perfectly steady and uniform motion for feathering wheels of great power, I would prefer, if my customer's purse was deep enough, to adopt the compound three-cylinder type of oscillating engine. In making some preliminary studies for a set of engines lately, to work up to 2,500 horse power, I adopted 1·42 inch high pressure, and 2·62 inch low-pressure cylinders, 7-ft. stroke, 35 revolutions, steam 90 inches. This gave a light load on the trunnion and a very equal distribution of power throughout the whole revolution. In this case, the high-pressure cylinder would be set in the center, with a low pressure on each side; the cranks would be set at 120°; the power would be transmitted from the engine to the wheel shaft through a drag link. In this case, the high-pressure cylinder occupies the place usually assigned to the air pumps and condenser; these I would make independent of the main engines, as also the feed pumps. I would also employ piston valves, two on each cylinder; this enables you to balance the cylinders properly on the trunnions. I would also employ in all oscillating engines the center of oscillation of which is directly under the shaft, two piston rods to each cylinder; these should be far enough apart to take the crank in between them and form the cup bolts for the brasses. This plan secures the necessary rigidity, fore and aft, and gives more burning surface in the neck bushes. There is no better study for a young designer who aims at a high degree of proficiency in his profession, than the oscillating marine engine, and I will leave it to you with this warning, never attempt to make a cheap oscillating marine engine. The boldness of design required, and the grace of motion that accompanies a well designed oscillator, do not admit of cheapening. The best efforts of such men as Mandely, Pen & Elder, have been lavished on this engine. They loved it, and it comes to us with many marks of their devotion. In fine, there is no place for second or third rate oscillating engines; it is either a grand piece of marine engineering, or it is a small motor to drive a donkey pump or small hoisting machine.

Another class of paddle engine, with the center line of cylinder directly under the shaft, and which deserves some attention is

The Staple Engine.

The principal feature in this engine is the return motion, and, as the name implies, they are tall structures. An engine of 8-ft. stroke would measure from the bottom of cylinder to the top beam of the guides 48 ft., and the piston rods would be about 32 ft. long. The Messrs. Todd & Magregor, Glasgow, made this form of engine a study and built many fine examples; and at present the plan is again revived in England in the shape of a six cylinder compound engine to which we will again refer further on. Some of the finest and largest examples by Todd & Mugregor were fitted with four piston rods, two being on each side of the cranks. The guides were carried clear down to the entablature and fitted with a guide block for the piston rods, about 10 ft. below the main guide block on the crosshead. This gave great stability to the rods when on the up stroke. The entablature of necessity standing close down on the cylinder covers, required some special designing, in order to make the piston accessible. In designing an engine of this sort of considerable power I should prefer to adopt the three cylinder compound, with the high pressure in the middle, the valve sheets on the after side of the cylinders, and the condenser on the forward side, an ordinary bucket-lift air pump having the full stroke of the engine could be used in this design. Feed, bilge and circulating pumps should all be independent. A six-cylinder staple engine is being built in England just now of considerable power. There are two nests of three cylinders each, the high pressure in each nest being placed directly under the crank, and the two low pressures placed fore and aft of it. There are four piston rods to each crosshead, two from the high pressure piston, and one from each of the low pressure pistons—the crank rods swings in a cage of piston rods. The condenser stands fore and aft in the center line of the engine, the pumps being long stroke bucket lifts, it is claimed for this arrangement that fore and aft stability is obtained, and span for the guide housings, without adding special framing for the purpose; but if the condenser be worked into the framing of the three-cylinder engine, as much fore and aft stability can be obtained, and besides secure a well balanced engine, the cranks being disposed at 120°. This is important in heavy paddle engines, especially when designed for feathering wheels and high speed. We have extended our remarks on the staple engine not because we expect this class ever to obtain favor on this coast, but because it presents many points of interest, for a young designer, affording more opportunities for design in trussed frame work than any other form of paddle engine.

As we are considering engines for ocean service it will not be necessary to refer to the horizontal form of paddle engine as in sea-going vessels. The center of gravity of this form of engine would be too high to make a practical design. The regular form of direct slide and connecting rod engines are therefore more or less inclined. Where the vessel has a considerable depth of hold, the cylinder may be placed diagonally fore and aft of the center line of shaft, as in the four-cylinder compound paddle engine by John Elder & Co., several of which were sent out to the Pacific Coast of South America.

The usual form of diagonal engine is the simple compound, one high and one low pressure cylinder, cranks at right angles, many fine examples of which have been built lately for service on the English coast and between the

Morgan's Feathering Paddle.

various ports on either side of the English Channel. In engines with vertical cylinder not under the shaft line, the form you are most familiar with, is

The American Beam Engine.

The construction and design of which you have examples at work all around from which you can gather materials for new designs. Study new frames for this class of engine, also the best method of building compound beam paddle engines. Amongst the engines with vertical cylinders, the side lever long held a prominent place. Those built by Napier for the Royal Mail Steamship Co. were fine examples of engineering, but the room they occupy and the great weight of framing necessary, have relieved the ponderous style from active service. The handsome elevations they made still give them a first place in our engineering picture books—where I trust they may find a place for many years to come to stimulate the taste and inspire the grand ideas of our rising engineers.

Before closing my remarks on the various forms of paddle engine, there is another form of engine I would like to notice briefly, on account of its simplicity and cheapness, and I think also its efficiency for moderate powers up to say 700 horses, indicated, viz.:

The Grasshopper Engine.

In this type of engine the cylinders are generally placed far enough aft of the shaft for the crank to clear them as it rotates, the vibrating levers are generally centered twice the length of the stroke forward of the center of the shaft. The full length of lever being three times the stroke of piston, thus for a 9-ft. stroke of piston, the crank would be 3 ft. center or at that point the stroke would be 6 ft. The air pump is placed midway between the connecting rod and the fulcrum of the lever, that would be 3-ft. stroke for the air pump, (sketch). Of course, I would not adopt such a plan for very large engines, as the unbalanced weights would be too great for the steam distribution to correct, but a very pretty and cheap design could be worked out on this principle for small powers—which I trust some of my young friends will set about doing these long evenings.

Having thus briefly reviewed the leading features of the various forms of engine employed in paddle vessels, we come now to the

Consideration of the Paddle Wheel Itself.

Every propelling instrument whether it be a paddle, a screw, or a pump, drives a ship by means of the forward reaction of the current of water which it sends backward. That reaction is transmitted through the propelling instrument to the ship, and when the ship moves at a uniform speed it is equal and opposite to the resistance of the ship.

Of different kinds of propellers in practical use that which has the simplest action is the feathering paddle, because it drives a stream of water directly astern, or nearly so. The radial paddle acts less simply and less economically, because part of the stream of water on which it acts is driven obliquely upwards, and the reaction due to the vertical motion of that water has no effect in propelling the vessel. The screw drives water astern in various directions more or less oblique; and the reaction due to the transverse component of the motion of each particle of water has no effect in propelling the vessel. The most important constant quantity in calculations respecting the action of propellers of every kind is the mass of a cube ft. of sea water, that is its weight in pounds, divided by the accelerating effect of gravity in a second. When velocities are expressed in ft. per second, the value of that constant is almost exactly 2. When velocities are expressed in knots per hour, the coefficient $5\frac{3}{4}$ is to be used, being $2 \times$ the square of the number of ft. per second in a knot per hour. The reaction of the stream of water acted upon by any propelling instrument is the product of 3 factors: 1st. The mass of a cube ft. of water. 2d. The number of cube ft. of water acted on in a second. 3d. The velocity in ft. per second impressed on that water by the propeller.

The number of cube ft. of water acted on in a second, is to be calculated by multiplying the sectional area of the stream by its velocity relative to the ship. This calculation might be made either before or immediately after the action of the propelling instrument takes place. The latter mode of calculation is the more convenient, because it appears from the results of experiments that the sectional area of the stream immediately after the action of the propeller is either very nearly or exactly equal to the area of the propeller itself projected on a thwartship plane; that is for feathering paddles simply the area of a pair of floats. For radial paddles the breadth multiplied by the depth of immersion; and for a screw the area of the disc less that of the boss. The velocity of the stream relative to the ship is the sum of two quantities; the velocity of the ship, and the velocity relative to still water of the stream driven back by the propeller, in other words, the apparent slip of that stream. For feathering paddles, the slip of the stream of water driven back is the same with that of the paddle floats themselves, because they press directly backwards on the water; but for a radial paddle wheel and a screw fan, owing to the obliquity of their action, the slip of the stream driven back is less than the slip of the paddle or screw. In the proportion of the square of the cosine of the obliquity of their surfaces to a thwartship plane, a ratio which is different for different parts of the stream of water acted on by the same paddle or screw. Having said this much on the principles of the action of propellers in general, we will for the present devote our attention to the paddle wheel and endeavor to set before you the leading principles that should guide the engineer in designing a

Pair of Feathering Wheels.

To determine the proper area of a pair of feathering floats for the paddle wheels of a given vessel to be driven at a given speed, with a given ship, the paddles working in water that is not sensibly disturbed by the ship. To solve this question the engineer must know, first, whether the vessel is so proportioned that her resistance depends on her augmented surface only. We cannot give the time at present to investigate the principles of skin resistance; this would lead us into an inquiry beyond the scope of this lecture, You must therefore be content with the statement that augmented surface is the whole area of the under water portion of the hull augmented by a multiplier, which is 1 + the means of squares of sines of obliquities of the water lines—that is, the fuller the lines of the vessel, the sines of obliquity would be greater and the augmented surface increased. Being satisfied, therefore, that the vessel is properly proportioned for the proposed speed, we divide the augmented surface by the ratio which the intended ship bears to the intended speed of the vessel; by the ratio which the intended speed of the centers of the floats bears to the intended speed of the vessel, and by the constant 566, the quotient will be the area required. In different conditions of the ship's bottom the constant division may have different values, which in the present state of our experimental knowledge, may be taken as ranging between 500 and 600. Take for example the steamer *Orizaba* (to which we lately fitted feathering wheels), her augmented surface is 8,560 square ft. Intended ratio of slip to speed of vessel 0.28, intended ratio of speed of centers of floats to speed of vessel 1.28—then $8,560 \div 0.28 \times 1.28 \times 566 = 42$ square ft. required area of a pair of floats giving 21 square ft. for a single float, which is the actual size of the float fitted. Having found the size of float or propelling instrument, we must now find the power required to drive the paddles. The prime factor in this problem is

The Resistance of the Vessel

in lbs. at her intended speed. Now the principles of resistance like that of augmented surface lie outside of the scope of this lecture, but its computation at a given speed is performed by multiplying the augmented surface by the square of the speed in knots and dividing by 100 for a clean bottom. Having obtained this resistance we must multiply this resistance of the vessel in lbs. by the speed of the paddle floats relative to the vessel, that is by the speed of the vessel plus the slip of ft. per second. This will give the required power in ft lbs. per second. Allowance must be made for the power wasted through slip, through wasteful resistances of the propeller, and through the friction of the engine. In making this allowance the practical engineer must depend upon his own experience. It of course varies in different ships, propellers and engines. In my own experience I find that it varies little from 60 %, so that as a probable value of the indicated power required in a well designed vessel we may multiply the net power by 1·6. The marine engineer, as we have just seen, has much to do with the

Hydraulics of Ship-building.

He should therefore accustom himself to the values and terms that are most convenient for the computations he requires to make. Now, an indicated horse-power is 550 ft. pounds per second and a knot is 1.688 ft. per second, therefore, an indicated horse-power is $550 \div 1.688 = 326$ knot lbs., nearly, or 326 lbs. of resistance overcome through one nautical mile, in an hour. If we estimate, then, the net or useful work done in propelling the vessel as equal to the total work of the steam, divided by 1.60, we shall have $326 \div 1.60$, in round numbers 200 knot lbs. of net work done in propulsion for each indicated horse-power. Hence, we have the following rule: Multiply the augmented surface in square ft. by the cube of the speed in knots and divide by 20,000, the quotient will be the probable indicated horse-power. The divisor in this rule, 20,000, expresses the number of square ft. of augmented surface which can be driven at one knot by one indicated horse-power and is called the coefficient of propulsion.

Having thus briefly stated the principles of propulsion common to all classes of propelling instruments, we may now turn our attention to the construction of a feathering paddle wheel. Having determined the area of the floats by the methods described, the breadth or length rather is commonly from twice to three times the depth. They are usually like radial paddles, rectangular and oblong—and sometimes have the corners rounded; and are made sometimes of wood (usually elm or pine) and sometimes of plate iron or steel. They ought always to be champered to a thin edge all round. The extreme depth of immersion of the lower edge of a feathering paddle ranges from 1 and ⅓ times to twice its depth. The pitch of the paddles or distance between them measured on the circle which passes through their centers of oscillation in some of the most successful examples, is from 1.6 times to double their depth or nearly so, and as this appears to give a sufficient hold of the water, a closer pitch is unnecessary, although I have met with examples in which the pitch is but little greater than the depth.

The mean radius of the wheel measured from the axis to the centers of the paddles, is seldom less than twice, or more than 3 and ½ times the depth of the paddles. A feathering paddle wheel continues to work efficiently at a deeper immersion, in proportion to its outside radius, than a radial paddle wheel, having in some cases been found to answer very well with half of its outside radius immersed. In the usual mode of framing feathering paddle wheels the centers and sets of arms are two in number only, and the arms in each set are equal to the number of paddles. The arms are commonly made to stand obliquely to the axis, so that they lie in two "dished" or concave conical surfaces. This enables the bearing for the paddle shaft journal which is carried by a bracket or projecting part of the vessel's side to be brought nearer to the center of gravity of the wheel than would otherwise be possible. There is sometimes only one ring to each set of arms immediately inside the circle of paddle, this is the case in these built for the *Orizaba*, and then the outer ends of the arms form curved spans to carry the bearings of the paddle journals.

In other examples there are two rings to each set of arms, one inside the circle of paddle and one outside; the intermediate parts of the arms being straight and having short spans projecting from them. The latter construction is no doubt the best for rough and stormy ocean navigation, because in the event of the feathering paddles being destroyed or disabled, radial paddles can be fixed on the parts of the arms between the two rings. Each of the paddles has fixed on its back two journal boxes lined with lignumvatie bushes or steel bars covered with brass secured in the spare of the arms. From the back of each paddle projects a lever, called the stem or stem lever, of a length equal to about 6 10° of the depth of the paddle. The ends of the stem levers are connected by means of guide rods of equal length, with the eccentric collar, which turns freely, either about a center pin fixed to the spring beam of the paddle box, or about an eccentric disc fixed to the side of the ship, and large enough to contain within it the paddle shaft and its bearings. The latter

(Continued on Page 356.)

THE FRANKLIN GIRDER!

BY FAR THE MOST ECONOMICAL OF ANY CONSTRUCTION MADE.

This new and economical Girder for Buildings and Bridges, made of any desired length and to sustain any required load, and guaranteed to be fully up to the sustaining capacity represented. The price of these Girders is ABOUT ONE-HALF the price of those of same length and same sustaining capacity in common use in this city. The valne of this invention has been most favorably commented on in full by most of the scientific press of this country, as the SCIENTIFIC PRESS, *Scientific American, Railway Review, The California Architect and Building Review, The American Architect and Builder*. A Girder 25 feet long, made for 17-inch wall, with about 2 feet of brick wall on it, is now in front of premises 231 First St., above Shot Tower. This Girder held on the top of the brick wall now on it, 117 Tons and 1,741 Pounds of Railroad Iron, at the Pacific Rolling Mills, piled directly over and between supports, and it would have held, in the opinion of experts 200 tons, as the deflection was not a quarter of an inch below the true arc. The foundation on which the Girder rested, settled 7 inches, so that the loading had to be stopped at the above weight.

The Price of these Girders, 25 feet Long, to Sustain 100 Tons as a Safe Distributed Load, $200.

THOSE IN COMMON USE NOW IN USE IN THIS CITY COST NOT LESS THAN $400.

And other sizes in like proportion. Every Girder guaranteed to sustain the load as a safe one; the breaking load being three times greater.

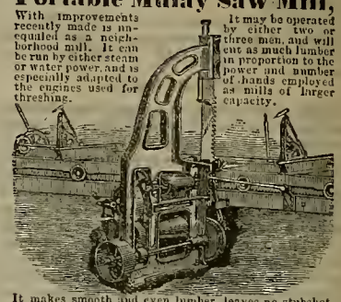
Prices for any Size and Sustaining Capacity given on Application.

P. H. JACKSON & CO., Makers,
2 California Street, and 231 First Street, San Francisco, Cal.

P. H. JACKSON,
Civil Engineer.

PATENT RIGHTS FOR STATES FOR SALE.

Portable Mulay Saw Mill,



With improvements recently made is unequaled as a neighborhood mill. It can be run by either steam or water power, and is especially adapted to the engines used for threshing.

It may be operated by either two or three men, and will cut as much lumber in proportion to the power and number of hands employed as mills of larger capacity.

It makes smooth and even lumber, leaves no stubshot, and will cut any sized log up to four feet in diameter.

It may be transported from one locality to another and re-erected ready for sawing in from two to three days, and can be made profitable in localities where there is not sufficient timber to justify the erection of a large mill. Send for descriptive circular, price, etc., to

CHANDLER & TAYLOR, Indianapolis, Indiana.

We also build the heavy Standard Circular saw Mill, with either one or two saws as well as the Pony Circular Saw Mill that is capable of being run with light power, We also build Stationary Engines of varied capacity; also, portable Threshing Engines.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered homs inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO.,

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

☞ Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

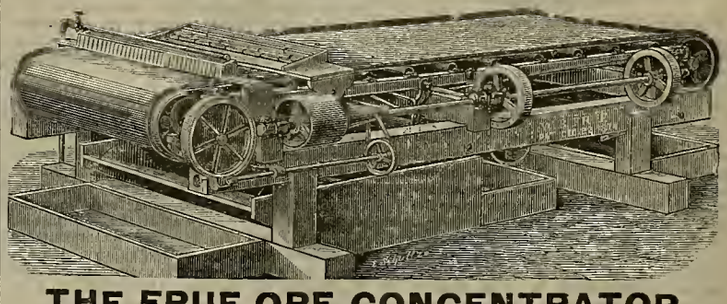
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

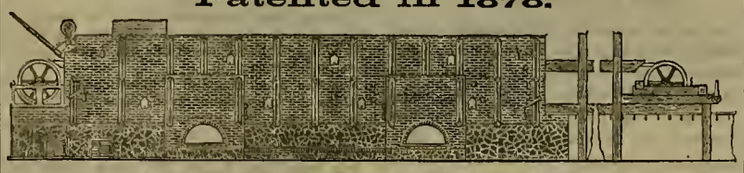
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand
SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

THE O'HARRA
CHLORIDIZING FURNACE.
Patented in 1878.



SIDE ELEVATION OF THE O'HARRA FURNACE.
This Furnace is Constructed with two SEPARATE HEARTHS, one for DESULPHURIZING and one for CHLORIDIZING the Ore.
BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.
An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.
A cheap Furnace to build and to run.
The process is essentially the same as the well-known Freiberg process; but this mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulpburize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor.
At Washoe and Ophir Tailings Mill it costs $1.10 per ton to work 40 tons in 24 hours.
At the Exchequer Mill, Alpine County, 20 tons are worked in 24 hours, at a cost of $2.61½.
Lewis Chalmers, of the Isabella O. & S. M. Co., Silver Mountain, Alpine Co., says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing at the figures there given, antimonial and arsenual sulphurate of silver up to from 84% to 95% of the assay.
SEND FOR DESCRIPTIVE CIRCULAR TO

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery
HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mils, Rock Breakers, Crushing Rolls, A lgamalin Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞ Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.
PRICES REDUCED!
PATENTS REISSUED 1868.
This "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.

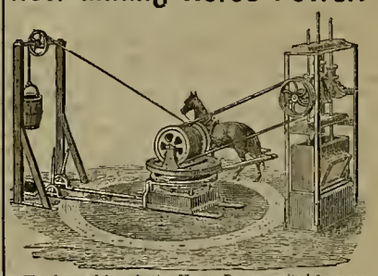
New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.

Marine Engineering on the Pacific Coast.

(CONTINUED FROM PAGE 353.)

plan which must be adopted where the wheel has outboard hearings, is nsed on the *Orizaba;* hut from the difficulties attending the working of such a large eccentric ring it should never he adopted in a new deeign.

All the guide rods except one, are jointed hy means of rounn pins to the eccsntric collar from which they radiate, that one called the driving rod, is rigidly fastened to the collar hy holts, or otherwise, and serves to make the collar revolve once for each turn of the paddle wheels. This is the mechanism used in Gallowery, otherwise called Morgan's feathering paddle wheel, and ie the only kind of feathering mechanism that is extensively used iu practice. The following is the best

Method for Finding the Center

About which the collar with the guide rods ought to turn: Let A, (in the drawing), represent the center of the paddle wheel; B C, the vertical diameter of the circle in which the centers of the paddle journals revolve. The most efficient kind of motion for the paddles to have is such, that in going into and coming out of the water, they shall move edgeways relatively to the current of water whicb their action produces—that ie relatively to current moving horizontally astern, with the velocity of the point B. In order that such niay he the motion of the paddles, their surface during their action on the water, ehould he parallel to lines radiating from C. We therefore draw W, W, to represent the low water line, cutting the circle B C, in D and E, then draw the straight lines C D and C E, these will show the proper positions for paddles leaving and entering the water respectively. The line C B already shows the proper position for a paddle at its deepeet immersion, which is vertical.

Draw D G,=B F,=E H, about 6·10° of the depth of the paddle, to represent the three corresponding positions of the stem lever, which is commonly perpendicular to the paddle, hut may, if convenient, he placed slightly obliqne to it, then find the center, K, of a circle travereing the three points G, F, H, that will be the proper positiun for the center of the collar, and K G=K F,=K H will esch he equal to the radius of the circle of pins in the collar added to the length of the guide rod.

To make eure whether the guide rods will, at all points, clear the inner edgee of the floate, produce A K to M, making K M equal K G, about M with a radius equal to a stem lever, draw a short circular arc cutting the circle B C—in L, then draw a paddle in the position corresponding to the position of L M of the stem lever; if the guide rod K M cleare the paddle in that position it will clear it in every other. When the feathering machinery is constructed according to these rules, the paddles, although they do not perform the rcquired motion with mathematical precision, approximate to it near enough for practical purposes throughout the arc E B D and for a short distance beyond it at hoth ends.

The greatest strees npon a stem lever and its guide rod occurs when the entering and leaving floats are about half immersed, as at D and E, in our diagram, and then according to the ordinary way of fitting up the mechanism there is thrust on the guide rods when the vessel ie driven ahead and tension when sbe is driven astern.

Mr. Scott Russel used to fix the stem levers on the fronts instead of the hacks of the floats and placed the center of the eccentric collar ahaft instead of afore that of the paddle wheel, so that there was tension on the guide rods when the ship was driven ahead and thrust when she was astern. The paddle wheels of the *Great Eastern* were so fitted, it was thought to he an arrangement more favorable to the etrength snd durahility of the rods than the ordinary arrangement.

Every paddle wheel, feathering or radial, ehould he properly halanced on its axis. It is had practice to fix counterpoises in the paddle wheel for the purpose of halancing the reaction of any part of the machinery on hoard. These produce great and irregular straine and endanger the eafety of the whole structure.

It was not my iutention when I began to prepare this lecture to devote so much time to the paddle wheel, and paddle wheel engines, and yet I have only succeeded in touching a few of the most prominent points of that branch of my euhject. My own conviction that this branch of marine engineering will have a future importance on this coast must he my excuse for setting you to thinking and I trust also to working on the subject. Advocating the adoption of swift paddle steamers for

Coast Passenger Work on this Coast,

Has been considered one of my weaknesses, hut now and again a new convert is made, and propositione that two or three yeare ago were laughed at are now considered, and compared with present plans.

I have here hefore you to-night a model for a vessel prepared hy me for the Southern trade of the Pacific Coast Steamship Co., and which they did me the honor to concider in all its hearings hefore ordering the *Queen of the Pacific*, now building for them.

This model was for a epeed of 18 miles per hour, wae to he of iron, 330 ft. long, 33 ft. beam and 20 ft. hold. By a peculiar section the sides were to sweep out in a curve to the guards, this would give great etahility in rough water and provide a great expanse of deck for passenger accommodation.

The engines were to be 3 cylinder oscillators ae already mentioned, of 2,500 horse-power, indicated. This vessel was to have a complete double hottom, the inner bottom being 3 6 from the onter, divided into four compartments; thie gave additional safety in case of touching ground.

But the principal object of this arrangement was to provide a means of keeping the vessel practicslly in the same trim for all oonditions of load. Thus the paddles would he desigued for the load line, that is with the water compartment all fnll, then as cargo was taken in, water would he pumpsd out, thus keeping the immersion of the paddles practically the same with all conditions of load.

Vessels of this clsss will be built yet for our coaet, and, in view of that fect, our time tonight has not been spent on an antiqnated type of the marine engine. The next time you and I meet we will have eomething to say about marine engines for screw propnlsion.

Notices of Recent Patents.

Among the patents recently obtained throngh Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

JOURNAL AND BOX.—Wm. H. Foye, San Francisco. No. 249,607. Dated Nov. 15, 1881. This invention relates to jonrnals and boxes for shafting and the framework therefor. The object is to secure a flexible frame and a line of flexible shafting witbout binding or in any way interfering with the rotation of the ehafting. It is specially adapted for use upon that class of agricultnral machinery which includes rotary or gang plows, pulverizere, harrows, and rotary cultivators of any description which require flexibility in order to conform to the irregularities of the ground over which they pass; but the fremework and ehafting are also for other uses and in other connections. The hearings for the shafts on the frame consist of spherical halls to receive the journals, these balls having a limited endwise motion in the bearings.

COMPOUND BARREL.—Hugo Mattullath, S. F. Dated Nov. 15, 1880. No. 249,650. Considerable difficulty is experienced in the construction of oasks for tbe transportation of oils or liquids of a penetrating nature, such as thoee derived from petroleum; and double wooden vessels either with or without an intervening filling have been employed, or wooden vessele having a close-fitting metallic lining variously oonstrncted; but all these are open to some objection. Mr. Mattullath'e invention relates to that class of compound barrele or packages in which an exterior case of wood is lined with metal. It consiste in certain details of constrnction of a combined wooden and sheet-metal cask. It is, in brief, a metallic cask having its end portions formed of sheets having tapering and gradually deepening corrugations from the edge to the chines or ends, combined with a central hand, to which the end portione are nuited, and hy whicb the length of the metallic cask is regulated and the whole strengthened.

HAY PRESS.—L. B. Lathrop, Hollister, Cal. Dated Nov. 15, 1881. No. 249,640. Thie ie a patent which covere certain detaile of construction, improving the press patented hy Mr. Lathrop on March 9, 1880. The prese ie a horizontal one, made of iron, and is designed to be permanently placed upon a four-wheeled wagon; and when in use, the wheels are locked, or the wagon is otherwise etaked to the ground, so that it is immovable. Mr. Lathrop doee good work with this press, and tbese new improvements make it still better. It would require elaborate engravings to ehow all the little points devised and carried out hy the inventor.

ADDING MACHINE.—P. C. Forreeter, S. F. Dated, Nov. 15, 1881. No. 249,606. This invention relatee to that class of adding machinee, the design of whiob is to record the sums of snccessive figures, by mechanical appliancee without any other mental operation than is necessary to work the machine. The principle of the invention is the operation of needles npon dials by means of a key hoard through intermediate mechanism, whereby the escapement governing the needles ie regulated to respond to the action of individual keys, denoting the nine digits. The mechanism of the devics ie very simple.

VEHICLE GEAR.—Geo. C. Buckland, Tulare, Cal. Dated, Nov. 15, 1881. No. 249,581. Mr. Buckland's invention on vehicle geare has for its object eimplicity and economy in conetrnction, together with durahility and effectiveness in nse. These improvements consist in a peculiar constrnction of the springs, and on the means of eecnring them to the axle and head block, the latter, of which, ie especially adapted to receive them; also in a croes hrace and a novel center spring riveted to said cross hrace, and extending forward under the axle and up on front, past hoth axle and head hlock, and hack upon itself, forming a spring loop throngh which the king holt passes.

THE Sutro tnnnel is gradually heing pnt in excellent repair. Old and shattered timhers have everywhere heen replaced hy new ones, and the sub-drain is kept in excellent order.

News in Brief.

A WILDCAT four and a half ft. long, and weighing 45 lbs., was killed near Lafayette, Contra Costa county, a few days ago.

AT a meeting of the directors of tbe Denver and New Orleans railroad the road was definitely located hy way of Pnehlo.

CINCINNATI finds great comfort in the helief that Vanderhilt and Gonld, working as rivals, are ahont to make that city a great railroad center.

THE total loss over the whole province of Ontario, Canada, by bush fires during the past season is estimated at hetween $10,000,000 and $15,000,000.

GRANT is said to bave made a round $500,000 out of his railroad connectione this year. Gossip always has a fondness for round numbers in theee matters.—*Philadelphia Press.*

THE *Whitehall Review* is reeponsible for the rumor that the Marqnis of Lorne and his illnstrious spouse may ultimately replace Earl Cowper and Conntese at Dnblin.

THE reports of Guiteau's trial excite tbe ntmoet astonishment among the English lawyers that such continued violations of decency are permitted in court.

THE San Jose Board of Education bas voted $500 for the pnrchase of type, cases and other printing apparatus, intending to have the art of printing taught in the public schools as a regular branch of education.

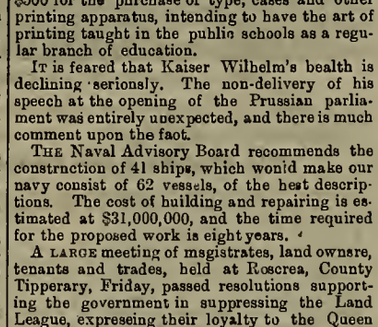
IT is feared that Kaiser Wilhelm's health is declining seriously. The non-delivery of his speech at the opening of the Prussian parliament was entirely nnexpected, and there is much comment upon the faot.

THE Naval Advisory Board recommends the constrnction of 41 ships, which wonld make our navy consist of 62 vessels, of the best descriptions. The cost of building and repairing is estimated at $31,000,000, and the time required for the proposed work is eight years.

A LARGE meeting of msgistrates, land owners, tenants and trades, held at Roscrea, County Tipperary, Friday, passed resolutions supporting the government in suppressing the Land League, expreseing their loyalty to the Queen and Constitution, and thanking the oonstahulary for their conduct in the late crisis.

Removal of Patent Agency and Newspaper Offices.

October 20th the patent agency and newspaper offices of Dewey & Co., were removed to the northeast corner of Front and Market Sts., occupying a large space on the upper floor, where we have spacious and pleasant rooms for the accomodation of our increasing business. Our apartments will have two entrances as shown in the following engraving: Our stairway, No. 252 Market St., and our elevator, No. 12 Front St.



☞ Take the Elevator at No. 12 Front St.

Visitors will find it better to step around the corner from Market St., to the elevator rather than ascend the stairs. Old and new friends are cordially invited to give us an early call in our new quarters.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissiou of agents

BOOKSELLERS, STATIONERS, ETC.—Messrs. Payot, Upham & Co., No. 204 Sansome Street, are one of the oldest, most enterprising and reliable firms in the hook and station ery trade in San Francisco. Scientific, industrial and foreign publications are a specialty with them. They are also noted for their first quality of blank hook and fine station ery line of goods.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

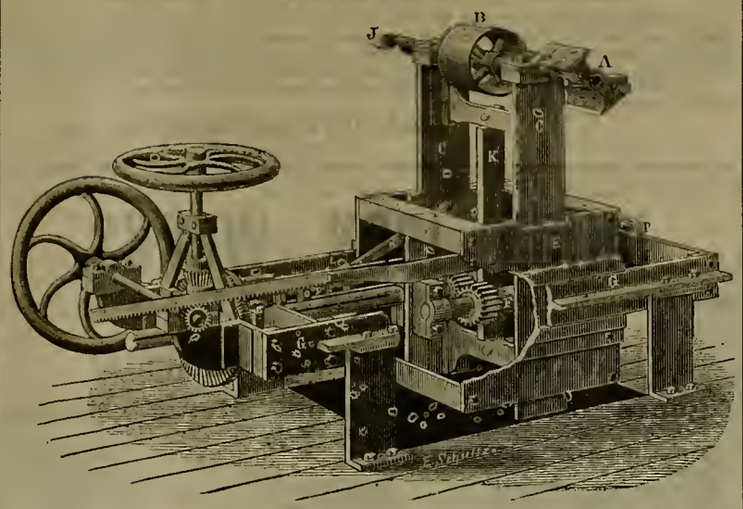
LEPLEY'S FRAMING MACHINE.



The above cut represents the Framing Machine invented by ISAAC LEPLEY, of Amador City, Cal. For perfection and rapidity of work it has no equal. Any form of cut, tenon, mortice, gain or dovetail in timber of any size can be made with exactness, and as rapidly as desired. It is complete in itself in all its parts, ready for the belt. The machine is simple in construction, and can be run by anyone of ordinary ability. Every mine requiring timber, and all mills where much framing is to be done, should have one, as a matter of economy. It will do the work of twenty men.

GOLDEN STATE AND MINERS' IRON WORKS,

COMPOUND OXYGEN — NOT A DRUG

A NEW TREATMENT for Consumption, Asthma, Bronchitis, Catarrh, Dyspepsia, Headache, Debility, Neuralgia, Rheumatism, *and all Chronic and Nervous Disorders.*

ACTS DIRECTLY upon the great nervous and organic centres, and *cures by a natural process of revitalization.*

HAS EFFECTED REMARKABLE CURES, which are attracting wide attention.

HAS BEEN USED BY Rt. Rev. John J. Keane, Bishop of Richmond, Va., Hon. Wm. D. Kelley, T. S. Arthur, and others, who have been largely benefited, and to whom we refer *by permission.*

IS STRONGLY ENDORSED: "We have the most unequivocal testimony to its curative power from many persons of high character and intelligence."—*Lutheran Observer.* "The cures which have been obtained by this new treatment seem more like miracles than cases of natural healing."—*Arthur's Home Magazine.* "There is no doubt as to the genuineness and positive results of this treatment."—*Boston Journal of Commerce.*

THE OXYGEN HOME TREATMENT contains two months' supply, with inhaling apparatus and full directions for use.

SENT FREE: a Treatise on Compound Oxygen, giving the history of this new discovery and a large record of most remarkable cures. Write for it. Address

ADMINISTERED BY INHALATION. Drs. STARKEY & PALEN, 1109 and 1111 Girard St., Philadelphia, Pa.

Depository on Pacific Coast.

WE HAVE ESTABLISHED A DEPOSITORY OF OUR COMPOUND OXYGEN HOME TREATMENT at San Francisco, Cal. This will enable patients on the Pacific Coast to obtain it without the heavy express charges which accrue on packages sent from Eastern States. All orders directed to H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., will be filled on the same terms on which we fill orders sent directly to our office in Philadelphia.

Patients ordering from our depository in San Francisco, should, at the same time, write to us, and give a statement of their case, in order that we may send such advice and direction in the use of the Treatment as their special disease may seem to require.

DRS. STARKEY & PALEN, Nos. 1109 and 1111 Girard Street, Philadelphia, Pa.

Construction of Geological Cross Sections.

In the construction of underground curves, two methods are in general use:

1. By equal thickness.
2. By equal (parallel) dips.

The calculated thickness of each stratum is rigidly preserved throughout in the first method, by making the curvature in each seam concentric to those above it. These curves are usually compound curves composed of circular arcs.

When the second method is employed, no attempt is usually made to preserve uniformity of thickness along the axes of anticlinal or synclinal flexures, the opposing dips are prolonged until they intersect, and the curvature sketched in to suit the fancy of the draftsman; but a combination of this and the preceding method is sometimes employed.

The difference between these two methods is illustrated by Figs. 4 and 5, in which the surface observations are identical, but the underground (hypothecated) curves vary widely. In Fig. 4 each stratum preserves a uniform thickness throughout, but in Fig. 5 the prolongation of the opposing dips produces an augmented thickness along the synclinal and anticlinal axes.

As it is evident that the first method will show the minimum depth of any coal in the basin, and the second the probable maximum depth—in all but exceptional instances—a combination of these two methods is apparently preferable, as more nearly approximating the probable underground curvatures. Such a combination has been employed by some members of the Geological Survey in the construction of many of the sections in Pennsylvania.

But there is a serious objection to any system, involving in whole or in part the method of equal thicknessess, viz., *the gradual obliteration of the surface flexures in the underlying rocks.*

This is illustrated by Fig. 6, which is constructed partly on this system. It will be observed that the steepest dips are *along the line of observed exposures;* above and beneath this line the axes rapidly fade away, and can hardly be seen in the basal stratum. The same result obtains in the (restored) formations lying above the present surface.

Sections constructed on this principle (Figs. 4 and 6) will, therefore, always show the maximum curvatures along the line of observed dips. It is hardly necessary to say that any method uniformly giving these results must be essentially false. The apparent regularity of profiles so constructed lends false pretensions of accuracy to the section.

Under *one sequence of conditions only* does this method give results approximating the true underground structure. Having reference to Fig. 6, let us suppose the lower strata to consist of hard, massive sandstones, or conglomerates, and the upper rocks of soft slates or shales. If a lateral compressing (flexing) force acts upon this series, the lower massive formation will yield in curves of large radius, while the overlying softer strata compressed in the trough thus formed will be thrown into a series of crimplee resulting in flexures similar to those shown in the section.

If, on the contrary, the observed dips in the upper rocks are in hard strata underlaid by softer rocks, these latter would suffer the greatest contortion, whereas the construction shows them nearly flat.

I have lately made a series of experiments on rock contortion, by artificially compressing layers of clay, paper, India rubber, wax, etc., and have attempted to deduce laws governing the relationships of the resulting curves, which might be practically applied to geological sectioning; but the factors involved are so numerous and vary between such wide limits, that it seems an almost hopeless task. I have, however, arrived at some general conclusions that may be of service.

1. The subordinate flexures of the sub-basins in a synclinal of soft rocks underlaid by a hard resisting formation, decrease in sharpness towards this basal rock.

2. If a series of soft measures underlies the hard formation, it may be contorted by a series of flexures bearing no relation to the upper series.

3. Where large masses of approximately uniform hardness are contorted by compression, the resulting curves bear close complementary relations to each other. (See Fig. 5)

The first of the above propositions has already been referred to on a preceding page. When these conditions obtain, as in the anthracite coal basins, the coal-measure rocks are crimpled and distorted while their hard basal plate of conglomerate has been arched into curves of large radius, with flat dips, as proved by diamond drill-holes. When these conditions obtain, the method of equal thicknesses, or a modification of that method (Figs. 4 and 6), will give curves more nearly approximating the underground structure than any other method.

Fig.4.

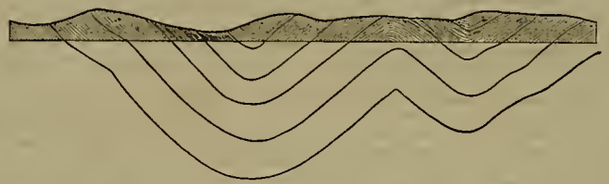

Fig.5.

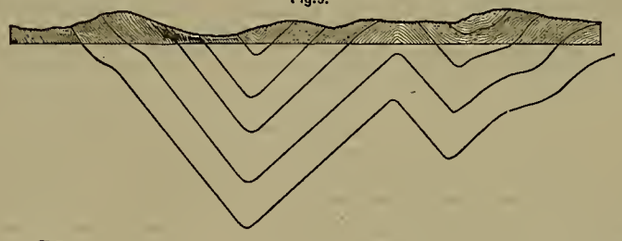

Fig.6.

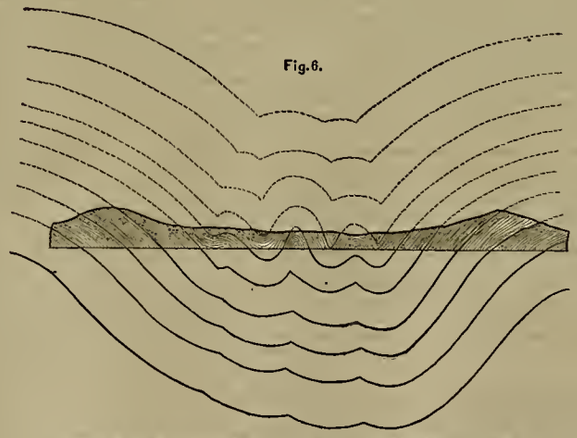

PROFILES OF GEOLOGICAL CROSS SECTIONS.

On the Lehigh river we find a striking exemplification of the second proposition. At Slatington the lower Silurian (roofing) slates, No. III, are twisted and contorted by a complex series of overturned flexures. Above these come the hard sandstones and conglomerates, No. IV, forming the mountain, dipping down in gentle curves of larger radius beneath the softer upper Silurian strata of Hazardville and Bowmansville. These latter are twisted, faulted, and overturned, but these flexures can have no possible relation to those in the roofing slates, lying 5,000 ft. beneath, and separated from them by the hard rocks of No. IV, which reflect the minor flexures of neither the former nor the latter. Under conditions similar to these it is of course utterly impossible to indicate the curves of the lower formation from any data obtained from the upper rocks.

The conditions of the third proposition are strikingly shown by cross-sections of the coal measures in some parts of France, in which the various coal seams are bent in a series of parallel zig-zag lines. Here the second method, *i. e.* by equal dips, is peculiarly applicable.

When the observed dips are in a hard, massive formation underlaid by softer rocks, and underground curves are always indeterminable.

Too much reliance is often placed upon geological cross sections as a means of determining underground structure. In this their utility is limited, but as a means of estimating rock thickness, as a help to intelligent prospecting, and as a pictorial means of representing demonstrated and hypothecated structure, their value is great.

A CORRESPONDENT of the PRESS writing from Plano, Tulare county, says: I might call attention to the fact that there is an excellent and inexhaustible supply of granite on a spur of the foothills close by to this place, some 30 miles southeast of Visalia, and that a few miles further there is some excellent marble. Also, there is a hill with good magnesite ore rich in iron, none of which are worked.

AS TO the power and rights the miners have derived from the Government, the Amador *Sentinel* can see little room for argument. When the mining land was sold no reservation was made. It was well known that the water used in mining must find its way into the streams again, and that a certain proportion of the earthy substance would accompany it. For 30 years this mining has been going on, and no attempt of a serious nature has been made to interfere with it until the present year.

ALL the miners believe that the right to mine was conferred by the general Government, and unless reparation be made the miner, a State court cannot take from him his occupation and render his property valueless.

Blasting in Collieries.

It seems somewhat strange that after seeing the remarkable difference in product arising from the use of powder in mines, that the possibility of doing without it should ever be considered. Yet for many months the subject has been discussed in Great Britain. The government considers it a necessary step, in order to preserve human life, to insist that no one shall be in the mine when shots are fired. It seems the matter cannot be left to mine owners to decide, whether the mine is dangerous or not. Some persons advocate prohibiting entirely the use of powder in coal mines.

A meeting of the members of the Mining Association of Great Britain was held recently at the Westminster Palace hotel for the purpose of considering a circular issued from the Home Office, through Mr. J. Dickinson, the inspector of mines, to the proprietors of mines. The circular in question drew attention to the opinion expressed by the law officers of the Crown as to the interpretation of Sec. 51 of the Coal Mines Regulation Act, 1872, making it obligatory on persons ordinarily employed in the mine to be out of the mine when gunpowder was used for blasting purposes; and requested that the requirements of the act should in future be strictly carried out where heretofore they had not been observed. Mr. Alfred Barnes, M.P., the president of the association, occupied the chair, and there was a numerous attendance of delegates from all parts of the country. After a long discussion, the matter was eventually referred to a representative committee to be considered and reported upon.

Nearly 50,000 miners and others employed in collieries of South Wales and Monmouthshire were represented at a delegate conference held at Aberdare a few weeks since, when the Home Office circular as to shot firing in mines was considered. After a prolonged discussion, a resolution was passed expressing the opinion that, considering the hard nature of some of the seams being worked, and the almost insurmountable difficulties of the ripping of top and the cutting of bottom without the aid of explosives, to work a number of seams in the South Wales coalfield without blasting would be impracticable, and that with care and competency the present regulations for the use of gunpowder are sufficient. It was subsequently resolved to send copies of the resolution to the mine inspectors, and others. A deputation of the delegates waited by appointment upon Lord Aberdare to lay before him their reasons against the recently issued government prohibition of powder blasting in collieries, except when the colliery are all out of the working. His lordship, when Home Secretary, had charge of the Mines act, the Home Office construction of a section of which act is now the subject matter of dispute. His lordship acquiesced in the general tenor of the views of the deputation, and it was arranged to have a representation made upon the matter to Sir Wm. Harcourt.

So far as hydraulic mines not being run for the special benefit of the laborers, it may be said that the same will apply to farming, manufacturing, or any other occupation. They are carried on more particularly with a view to benefit the owners. In mining, white men receive from $2.50 to $3 per day, which is far above the rate that is paid for farming or manufacturing labor. The working miners complain of the injunctions, because they are kept from pursuing their occupations for an indefinite length of time, and are prevented from gaining a livelihood. They do not complain of the wages paid them when they can work, and are then as prosperous as any working men in the State.

CALVIN PELCIVAL died at Washington, Nevada Co. on Nov. 15th. Mr. Percival was a miner of extensive experience, having visited the mines of Australia, Montana and many other parts of the world, in addition to California. He made money rapidly and was once very rich, but, like the majority of old timers, he spent the greater part of it in prospecting.

California Water Rights.

A decision was rendered Nov. 3d, by Judge Brundage of the Superior Court of Kern county, in the great water suit of Miller & Lux et als. vs. the Calloway Canal Co., in favor of the defendants. In its relation to the agricultural interests of the southern part of the State, the case is of supreme importance. The plaintiffs are the owners of certain swamp lands lying between Buena Vista and Tulare lakes; Kern river is an effluent of Buena Vista lake. In times of high water, this lake sometimes overflows these lands or fills some ill-defined channels that meander through them. Upon this circumstance they claimed the waters of Kern river as riparian owners, and brought an action for an injunction to prevent the diversion of water through the Calloway canal. The defendants claimed the water as prior appropriators to irrigate public lands along said canal. Similar suits were commenced against all the other irrigating companies diverting water from Kern river. Had the plaintiffs been successful, the irrigating system of Kern valley would have been at their mercy, as they would virtually have owned the waters of the river.

The decision of Judge Brundage has apparently been prepared with great care, and after long study of the subject and search for authorities. It involves the vital point of riparian ownership in water, as defined by the present English law against the prior appropriation rights, which were recognized in the older English law, and are in force in all countries where irrigation is practised. The decision of Judge Brundage is published in full, in a supplement to the *Kern County Californian*, of Bakersfield, where all who desire the opinion in extenso may obtain it. It will serve the purpose of the majority of our readers to have the leading points involved and the decision thereupon, and these we present in the form of an abstract of the decision, made by the Bakersfield *Record*, as follows:

The plaintiffs claiming as riparian owners, contend that the common law of England is in force in this State, and that by its provisions, a riparian owner of a stream not navigable takes the land to the center of the stream, and that the right of the use of the water flowing over the land is an incident to his estate, and he has a right to have the water flow, as it was wont naturally to flow, without diminution or alteration. The claim for damages was abandoned, and the suit is now one in equity for an injunction alone.

The defendant claims that plaintiffs are not riparian owners, and even if they were, the doctrine of riparian rights for which plaintiffs contend, has no application to California on account of the physical condition—that the law in this case is the law of appropriation to beneficial uses, and not the modern English doctrine of riparian law.

The Court says: "The plaintiff's lands consist of two parcels lying in Buena Vista swamp: one parcel, lying near Tulare lake, some 50 miles below the head of the Calloway canal, through which the defendant directed the water of Kern river, and the other parcel, higher up in the swamp, about 20 miles below the head of the Calloway.

"The defendant claims the right to divert the water for irrigating public lands along the Calloway canal, as a prior appropriation, having made the appropriation before the plaintiffs acquired title to their lands.

"The plaintiffs derived their titles to their lands as swamp and overflowed land from the State of California, under the reclamation law of the State by patents bearing date subsequent to the appropriation for the Calloway canal."

One of the principal points in the decision is that "riparian rights are subordinate to rights of appropriation," and in support of his views on this subject, the Court quotes numerous authorities to show where the rights of appropriation have attained a precedence over the riparian law. He holds that the common law of England, adopted by the Legislature of California in April, 1850, was adopted only so far as it conformed and was consistent with our institutions and forms of government, and was applicable to our conditions. The Court says:

"The doctrine of riparian law, which had been found applicable and suitable in England, and possibly to the abundantly watered States east of the Rocky mountains, if enforced in the State of California would condemn to perpetual barrenness nearly the whole of the great interior valleys.

"The courts of New York had decided that although the Legislature of that State had adopted the common law of England, and that law declared that no stream was navigable beyond the ebb and flow of the tide, did not apply to this country, where the physical conditions are different—that it could have no application to a continent full of great navigable rivers and fresh water lakes, where the tide does not ebb and flow, but which are really navigable waters."

The court holds that the law of appropriation is strengthened by custom and the acquiescence of both the State and Federal governments, the same foundation upon which rests the whole superstructure of the common law of England. "'The common law of England,' says Blackstone, 'is a law built up from custom, and it is one of the characteristic marks of English liberty that the common law depends upon custom, which carries internal evidence of freedom along with it, that it was probably introduced by the voluntary consent of the people.'"

"It is generally held throughout the Pacific States and Territories, that the right to water by prior appropriation for any beneficial purpose, is entitled to protection. * * If the water had been diverted before plaintiffs bought their land, they purchased it with a knowledge of the policy of the government and the grant gave them no rights to the water. If, when they purchased the land, the water was still flowing in the stream and unappropriated, and they needed it for their farm, they had nothing to do but appropriate it and apply it to their own uses."

"Even upon the strict doctrine of riparian rights, as declared in the decisions of States where irrigation is not a necessity, the defendant is entitled to the same privilege with reference to the water of Kern river as a 'supra' riparian proprietor. This gives it the right to make a reasonable use of the waters to supply all natural wants, of which, upon these desert lands, irrigation is one, and the defendant's appropriation of the water here does not exceed such reasonable use. * * The defendants might, if necessary, have taken for this and other natural wants all the water in the river, but the proof here is that only a reasonable portion of it, in fact, was taken."

"I am inclined to the opinion, from the hurried review that I have been able to make of the apparently conflicting authorities on the subject, that the true rule in a case of this kind is that a court of equity will not take jurisdiction on a bill for an injunction when the title is disputed, without first requiring the complaining party to establish his title of law, and this the plaintiffs have not done.

"I am also of the opinion that the plaintiffs, although the full period of the statute of limitations has not run, have been guilty of such laches that a court of equity ought not to entertain a bill for an injunction. Some of the titles under which the plaintiffs claim and on which they rely, were obtained January, 1876, and the others at different times down to August, 1878. If these plaintiffs had any right of action at the time they commenced this suit, they had an equally valid one more than three years before. They stood by and saw the defendant expending vast sums of money in constructing its irrigating canal without objection or protest—without seeking in any manner the interposition of a court of equity, and it does not seem equitable to give the extraordinary remedy of an injunction which will necessarily render valueless this expenditure, destroy the canal and condemn the whole country along its course, now converted by the money and enterprise of the defendant from a desert into a garden. This view seems to be abundantly supported by authority.

The Car Shops of West Oakland.—The work on the Central Pacific car shops in the new yards is fairly under way. The foundations on the east side are all laid and squared on the top, the south wall of the west wing up eight or ten feet, the corners laid, and this morning the bricklayers commenced work on the north wall. The building is 153 ft. front and 80 ft. deep in the main structure with a west extention of 80 ft. more, making the center portion nearly 160 ft. square. There are 15 men employed, and over 400,000 bricks will be used. The work is all first-class, and is under the supervision of Mr. Geo. Nagle, the contractor. In front of the building is to be placed a transfer table, upon which cars can be moved to any of the entrances of the main building, which is to be fitted with tracks throughout. At the southwest corner of the building is to be erected a brick engine house, 56x22, in which there will be a stationary engine to run the lathes and other machinery in the shops. The new round-house, which will be erected south and west of this building, will be commenced after the bricklayers are through with the present work. The building will be complete in every respect, and a great improvment on those now in use. The building at the foot of Wood street is ready for the roofers.—*Oakland Tribune.*

The hydraulic pumps at the Chollar-Norcross-Savage shaft, which was described and illustrated in a recent number of the Mining and Scientific Press, will soon be made to run by a natural flow of water led to the feed pipe from the works of the Virginia & Gold Hill Water Co. When this change has been made there will be no need of the present surface apparatus by means of which a pressure is brought to bear on the water in the feed pipe, and a return column for the replenishment of the feed pipe brought to the surface. The flow of water down the feed pipe will run the pumping apparatus at the 2400 level, and all the water will pass out at the Sutro tunnel level.

Chas. Jones, one of the two miners who discovered the famous group of Robineon mines, in Colorado, died while drunk in a Leadville saloon. He then owned a quarter interest in seven mines out of the 12 constituting the Robineon consolidation, from which the late Lieutenant Governor Robineon made his fortune of over $1,000,000. The heirs of Jones live in Vermont, and not being informed of the great value of his estate, were induced to accept $1,200 for an estate really worth $250,000. A legal contest is to follow.

The mining situation on the Forest Hill and Iowa Hill divides, Placer county, is very satisfactory.

The Sebillot Process.

Sulphuric Acid and Ores.

It is a long-established fact in chemistry that heated sulphuric acid will completely disintegrate ores. That agent is used by the United States assay offices for the purposes of assaying, and it is quite generally acknowledged to be the most effective disintegrator known to chemistry. Its application in the treatment of ores on a large working scale has, however, thus far been impossible; for no means has been applied for conserving the evaporated acids, and its heavy cost would preclude its use even at those points where it is cheapest, and much more in the larger mining States, where it sells at over $100 per ton. These obstacles to its use appear to have been effectually surmounted by M. Sebillot, an eminent Paris engineer, through patented contrivances by which he condenses so much of the acid as evaporates and reproduces such portions of it as go into combination with the ore in course of treatment, both the condensation and the reconstruction being, it is claimed, effected at a comparatively nominal cost.

The complete reduction of the ore is effected through mixing it, in a pulverized condition, with from one to one and a half times its weight of strong sulphuric acid, and subjecting it to a moderate heat until the acid is entirely evaporated. The reduced mass is then subjected to processes regularly practiced in metallurgy, and the entire contents of precious and base metals are obtained in a pure condition, the iron being available for the manufacture of steel without further change. As already stated, the acid that has been used in the conversion of the ore is saved or re-made, with but a trifling loss, and is available for repetitions of use without limit.

The inventor claims that the cost per ton of this procuring all the metals, precious and base, each in a chemically pure condition, is far less than that of procuring the gold and silver alone under the best and most carefully operated processes at present known; and, considering the nature and economics of the process and its exemption from destructive temperatures or expensive agents, there seems to be good *prima facie* evidence that this claim may be well founded. The process professes to be equally adapted to all kinds of ores. For sulphurets it should possess a special adaptation, inasmuch as it conserves the sulphur and includes an apparatus for converting it into sulphuric acid at a small part of the cost common in the leading acid works of our manufacturing cities. In some parts of the country this would be a most important advantage; as, for instance, in North Carolina, where the sulphur could be extracted from now worthless pyrites and made into sulphuric acid for the manufacture of phosphate manures, the residuum of the ore being treated for its base metals and such gold or silver as it might contain. When it is considered that large masses of those now useless ores contain in each ton about 950 lbs. of sulphur, and 950 lbs. of iron, and from $2 to $12 in gold, the profit that would accrue from such treatment becomes apparent. It is computed that Colorado ores contain, on an average, about 250 lbs. of iron per ton, 200 lbs. of zinc, 80 lbs of copper, and 300 lbs. of sulphur; which, being claimed to be recoverable under this process, would give it a most important advantage over the best existing methods.

Miners will perceive at a glance that, if this process can be successfully applied, a great revolution in mining must result. A method that gives the assay contents of procuring 60% to 95% of those metals, and that gives in addition all other minerals in the ore that have any value, would confer a largely increased value upon all ores and make profitable a vast extent of mining that can now be conducted only at a loss. It would not only increase the value of mining property, but would revive mines that have been abandoned because of the low grade or the refractory nature of their ores. Vast quantities of stubborn ores in Colorado that, while assaying $40 to $75 per ton of gold and silver, are worthless because no process can reduce them at a profit, would then yield a good return to the miner. Indeed, it is not easy to put a limit to the extension of mining that must follow the successful application of such a process. However, forecastings may be very properly deferred until the Sebillot method has had a fair trial, which it appears likely to have at an early day. A company has been formed for working the process, and preliminary works have been started at Denver for perfecting the working details, preparatory to the erection of works on a large scale.

So long as we are accustomed to announcement of "improvements" in reduction which turn out to be failures, it is proper to regard all new processes as on probation until their merits have been demonstrated by working results. It is only just, however, to M. Sebillot's method to acknowledge that it carries on its face more probability of success than new processes generally do. It comes from an engineer of acknowledged ability and character in his profession. It attempts nothing new in chemical processes. Indeed, beyond the condensation of the acid vapor and the reconstitution of acid destroyed—which from expert evidence appear to be accomplished with success—the process includes nothing that is not commonly done in industrial operations. What is new seems to be the simplest part of the process, and what is old has been put beyond doubt by experience. This much must, in justice, be conceded in advance of trial; for the rest we must wait for the verdict of results, though from what we know of the process, we incline to an anticipation that the results will largely justify the inventor's claims.—*N. Y. Commercial Bulletin.*

Brief Mining Notes.

Hon. Robt. Ingersoll, of lecture fame, is interested in mines near Chloride, N. M.

The Copper Queen mine, Arizona, ships 300 tons of copper per month.

A rich strike is reported at the Burning Moscow mine, San Buenaventura.

If Eureka does not have a mining boom next spring, then all the signs will fail.

The Prospect Mountain tunnel, Eureka, has now been run a distance of 1,775 ft. When completed it will be 3,000 ft. long.

The Eureka mill, one of the largest and most complete in Nevada, has been "hung up" for a long time.

D. B. Lyman, Supt. of the Pacific M & M Co., has been appointed superintendent of the Utah mine, vice Rooney, who declined to accept.

The bins at the Richmond company's works are overflowing with charcoal, and there are some 40,000 bushels piled up in sacks besides.

Reduction works are a necessity in Tucson. Capital is abundant, and will not hesitate to come, if prospectors and interested parties will direct their attention to demonstrating the existence of large deposits of low-grade lead ores.

A correspondent writing from Poormen's district says: While we blast and pick and shovel the ore into the bucket, as it comes sliding down the incline, we forget about bacon and frijoles, and overalls and rough blankets, other petty discomforts, and talk about Europe and World's Fairs as familiarly as though they were things of the present; and although we do not build castles in the air, we lay plans for a good many under ground.

Daniel Collins, who lived in Humbug Canyon, about three miles below Damascus, for the last 25 or 30 years, one of the oldest residents of that locality, was found dead in his cabin last Monday. His body was so badly mashed that his bowels protruded, which led to the conclusion that he must have been caved on in his mine, and extricating himself had crawled in his cabin, some 2,000 ft., in his badly crippled condition, and there lying down in an exhausted state, died.

The Antelope mill at Del Monte station, recently bought by Gov. Blaisdell, is a very handsome brick structure, with a battery of 20 stamps, the boiler and engine and all the machinery complete. It was erected during the mining excitement in Aurora several years ago, at a cost of over $200,000, and was run but a short time. The Governor now has a force of men at work putting in new foundations and arranging everything for an extended run. He purposes working ore from his West Humboldt mine.

The miners paid the Government for their lands, just as the agriculturists did, the only difference being that the miners paid $250 per acre as against $1.25 by the ranchers. The miners also were the first to occupy the public domain. In the early days everybody came to California to mine for gold. Few, if any, came to till the soil. It seems harsh in the extreme that the men and industry which peopled those golden shores and gave birth to a sovereign State, should be forced to take back seats in the end.

Gold and Silver in Norway and Sweden.—Two Englishmen, Mr. W. Gray and Captain M. R. M. Griffith, R.N., have recently obtained a concession from the Norwegian Government to search for alluvial gold in the rivers of Finmarken, in the north of Norway. Every year several parties of Norwegians have been engaged in washing gold in these rivers, close to the Russian frontier, the only condition which the Government imposes being that the quantity of gold extracted is duly reported. The profits, however, of these enterprises have hitherto been very small; in fact, only just paying for labor. Silver lodes of more than ordinary richness have also been discovered in the north of Norway, and offered to the Norwegian public, and it is said that the formation of a company is contemplated with a view to work these lodes. When it is considered that the silver-works of Kongsberg, now belonging to the Crown, were for more than 200 years worked with a very small surplus, and that the cost of producing an ounce of silver at the Tinoren Silver works was equivalent to spending such a quantity in gold, we cannot be surprised that the concern is not received with very great enthusiasm in Scandinavia. The prospect of interesting Englishmen in the alluvial gold deposits in Finmarken has therefore met with much favor, the Norwegians being evidently of opinion that our capitalists have more money to expend on such operations than their own. In this connection it may be mentioned that gold has also been lately found in not inconsiderable quantities in the copper mine of Falu. In some instances the lumps brought up with the quartz in which it is imbedded have been, it is said, about the size of peas. The discovery is, however, not considered of any financial importance, but looked upon merely as a geological curiosity.—*Iron.*

MECHANICAL PROGRESS.

Erroneous Ideas of the Steam Engine.

Every first-class mechanical engineer can remember the time when the commonest terms in use about steam and its mechanical employment were unknown Greek and Latin to him; so no excuse is necessary for the following answers to questions by young mechanics that have been preferred more than once. In theory and in principle there is no machine in use that is less complex and more readily understood than the steam engine. Its principle is founded on the plainest abstract rules and the most obvious practical experiments in natural philosophy, but in practice the numerous transformations of the steam engine, and the apparent intricacy of its mechanism appal the earnest inquirer who imagines that the text books do not give him half the facts, and that engine builders withhold mysterious truths which none but the initiated can understand. This is not so, but more befogging about the steam engine has come from the misuse of terms than from the withholding of facts.

The two Systems of Steam Engines.

There are two general systems of using steam in engines that give two divisions of steam engines known, in common parlance, as "high pressure engines" and "low pressure engines." These terms are, however, not only indefinite, but calculated to convey a wrong idea. To the impractical inquirer the term "high pressure," as contradistinguished from "low pressure" implies the use of steam at a much greater energy to the square inch than "low pressure," and suggests possibly greater danger from explosions. But the fact is that there are "low pressure" and "high pressure" boilers which carry steam of the same general pressure. A "high pressure" boiler is not, necessarily, a dangerous one, neither is a "low pressure" boiler necessarily safe.

The proper distinguishing terms are "non-condensing" and "condensing" engines, the "non-condensing" corresponding to "high pressure" and the "condensing" to "low pressure."

When the steam used in the engine cylinder has performed its work of driving the piston from one end of the cylinder to the other it is allowed to escape either into the atmosphere or into an exhausted receiver known as the "condenser." The "non-condensing," or misnamed "high-pressure" engine exhausts its steam directly into the atmosphere, striking against it with such force as to produce a noisy concussion heard at every stroke of the piston, and particularly noticeable on locomotives on starting and while getting under way. The extent of this force can be readily understood when it is remembered that the atmosphere presents an obstacle against the steam of a weight of 15 lbs.—or nearly—for every square inch of area. It is evident, then, that the productive power and useful energy of the "non-condensing" engine is short of just that amount of effectiveness—in other words, that the energy necessary to displace the atmosphere and remove its pressure by the escaping steam is not used in the propulsion of the engine and its load.

Comparative Value of the Two Systems.

At first sight it would appear to be demonstrated that the "non-condensing" engine would, of course, be more expensive in use than one that did not have this drawback; but this is not necessarily so, for some other elements than those of the first cost of steam and its direct effectiveness are concerned in the problem of how to produce and use steam power economically. If this were not so there would be comparatively small advantage in the variety of styles of steam engines; and yet it is apparent to the most cursory observation that steam engines must be designed for their special place and work as much as road vehicles should be—the coach, omnibus, and truck team having only the most general characteristics in common with the buggy, racing gig and bicycle.

The "condensing" engine, on the contrary, exhausts its steam into a vacuum—as nearly a vacuum as may be produced by mechanical means—formed by exhausting the air from a vessel called the "condenser." When the exhaust steam from the engine has done its work of pushing the piston in one direction it passes instantly into this vacuum, where it is met by a jet of cold water, instantly condensing the steam, thus reducing its volume from about 1,700 to 1, the proportion between water in a vaporous or gaseous state and water in a solid condition. At the same time the latent heat in the steam leaves the water at a proper heat to be fed back to the boiler, the temperature being from 100° to 120°.

But the addition of the condenser, the necessary air pump and appurtenances make the condensing engine more complicated and cumbersome than a non-condensing engine, and somewhat limits its use, and greatly adds to its first cost. These facts have restricted the general use of the condensing engine, and almost confined its employment to the propelling of large steamships and the driving of machinery in extensive manufactories. There is

Another Popular Error

Relating to steam engines, and their work, and that is the common style of talking "horse power" in allusion to the power value of steam engines. This method of defining the energy of steam was originated by James Watt, who had no other handy and available comparison than the work done by Cornish horses in raising coal, men and water by means of winch and pump from the depths of coal mines. As his engine was primarily constructed to supersede, or to compete with the work of horses it was but natural that Mr. Watt should place their animal power in contrast, or comparison, with his atmospheric engine; and having ascertained that the best of the trained hoisting horses could raise 33,000 lbs. one foot in one minute over a single pulley, he adopted that as his initial or rudiment of power-measuring. From Mr. Watt and his works at Soho the "horse power" went out as the unit of steam power.

But modern engineers, although employing this term, do so with mental reservation, or at least mentally define it in the consideration of: Pressure per square inch. Area of piston in square inches. Velocity of piston. If nearer approximation is desired, other considerations are taken into the problem, as the point of cut-off of the admission of steam to the cylinder, the character of the valve gear, the amount of clearance, the diameter and weight of the flywheel, and other items relating to the normal condition and useful quality of the steam. For general and rough estimates, however, the practical engineer conveys to a brother engineer an idea of the power of an engine by stating the boiler pressure, diameter of piston and length of stroke.

How the "Indicator" is Used.

When approximate and nearly absolute results in the knowledge of steam use are desired, the "indicator" is attached to the steam engine cylinder. This is a small steam cylinder that takes the steam at the same instant the engine piston takes it, and, of course, with the same pressure; and while the engine piston is doing its work, the minister's piston is recording it, by means of attached mechanism on a sheet of paper. By having one of these indicators at each end of an engine cylinder, the reciprocating action of the steam in the cylinder is simultaneously recorded in the form of a diagram that, by right lines and curves, gives the data of the admission of steam, the point of its shutting off, the amount of its expansive energy, and the total of its work. Very accurate measurations have been made by this miniature instrument, but the diameter of the cylinder has an area of only about one inch, while that of the measured cylinder may vary from 6 or 10 square inches to as many square ft. By the use of this instrument, the determination between "nominal" (calculated) and "indicated" (real) horse power is found, the variations of which are very marked.—*Boston Jour. of Com.*

The Cost of Iron Castings.

When an individual, a firm or a company runs an iron foundry without a machine shop, or a boiler shop, or any other like attachment, it is very easy to determine just what it costs per pound to make iron castings. Again, when the proprietor of a shop buys all his castings, he knows to a certainty what they cost. But when an establishment consists of a foundry, a machine shop, and perhaps two or three other departments, the probabilities are that no accurate account will be kept of the actual cost of iron castings. The proprietor must of necessity know what are the net results of his work, but where a mixed business is carried on, there is no way to know exactly what castings cost, or what machine work costs, unless a separate record of every element of expenditure is kept for each department. A large portion of the shop owners are satisfied if the establishment is making money upon its aggregate business, without bothering themselves about probable elements of loss.

Relative economies are overlooked when a fair exhibition of general economy is apparent. Thus, it often happens that concerns making their own iron castings pay more per pound for what they use, all elements being considered, than the same could be procured for on contract with some neighboring foundry. Tell them that this is the case, and they will not believe it. Sometimes a shop of this kind takes an order for a lot of castings for outside parties at what is considered a fair price, and makes the unpleasant discovery when the order is executed that there is no profit, but on the contrary a loss in the transaction.

The effect of such an event upon the business habits of the proprietor is apt to be salutary.

It is often decidedly cheaper to buy castings, even in large quantities, than to conduct a foundry and make them.—*American Machinist.*

SHARPENING CIRCULAR SAWS.—The following method is recommended for sharpening a circular saw which has become blunted. The saw being set in motion, a fine cut file is held against the teeth until all are equably leveled. A pointed tool, or steel pen, dipped in ink, is then applied to the saw as it revolves, a little below the depth of the teeth, making a circle on the saw plate. The saw is then taken from the spindle and either remounted or screwed into a bench-vice between two washers of wood, which should reach within half an inch of the teeth. The teeth are then carefully filed to the line drawn with the tool or pen.

TO WIND a watch it is better to turn the hole downward, and let the small end of the key point upward. This will allow any little particles of dirt, metal or dust to drop out, and the watch will not need cleaning so often.

SCIENTIFIC PROGRESS.

The Prince of Planets.

We are indebted to the Providence *Journal* for the following description of Jupiter, which planet now nightly shines with unwonted brilliancy in close proximity to the glittering Pleiades: "This lordly leader of the starry throng now dominates the sky, and his four moons are plainly visible through a good field-glass. The dry climate and clear atmosphere of Arizona are peculiarly favorable to the observation of celestial phenomena, and if one of the observatories now located near the humid sea-shore, or in close proximity to smoking cities, were removed to one of our mountain peaks, the best results in astronomical discovery might be expected. Jupiter is morning star till the 13th of November, when, passing to the eastern side of the sun, he becomes evening star. If Mercury deserves the palm on the planetary annals of November as the hero of the transit, Jupiter will win equal renown for the most brilliant speech in his course, his opposition with the sun. This grand event occurs at four o'clock on the morning of November 13th, when Jupiter will be nearer to us than he will again before more than a year to come. He will then rise at sunset, being opposite the sun, and no one who looks at the eastern sky, almost as soon as the sun has disappeared below the western horizon, can fail to recognize the prince of planets as with majestic steps he treads his sparkling pathway toward the zenith. In brilliancy and size he exceeds every star then visible in the heavens, and wins from every star-gazer tributes of wonder and admiration at his magnificent appearance. He will be a superb object in the heavens during the frosty nights of November, when the moon is out of the way, and for three months to come he will outrival every member of the starry host in the nightly pageant. He is only 13 days behind Saturn in reaching the same goal, and passes the meridian when in opposition at 42 minutes past 11 o'clock, 40 minutes behind Saturn. Jupiter is now about 408,000,000 miles from the earth, instead of 591,000,000 miles, as when farthest away—183,000,000 miles, the difference in distance, is something our finite powers can form little conception of, but it is of significant dimensions in celestial distances. For the distances of the earth from the sun, more than 90,000,0000 miles, is the unit of measure for computing the distances of the fixed stars. Alpha Centauri, the nearest star in the myriad host, is estimated to be more than 200,000 times as far from us as the sun. In comparison with these distant shining orbs, Jupiter is our near neighbor, and his mean distance from the sun is not much more than five times greater than our own.

ELECTRICAL INSECT.—It is not generally known that there are insects which possess the peculiar electrical properties of the raia torpedo and *gymnotus electricus*. Kirby & Spence, in their Entomology, describe the *reduvius serratus*, commonly known in the West Indies by the name of the wheelbug, as an insect which can communicate an electric shock to the person whose flesh it touches. The late Major-General Davis, of the Royal Artillery, well known as a most accurate observer of nature, and an indefatigable collector of her treasures, as well as a most admirable painter of them, once informed me that, when aboard, having taken up this animal and place it upon his hand, it gave him a considerable shock, as if from an electric jar, with its legs, which he felt as high as his shoulder; and dropping the creature, he observed six marks upon his hand where the six feet had stood. Two similar instances of effects upon the human system resembling electric shock, produced by insects, have been communicated to the Entomological Society by Mr. Yarrel; one mentioned in a letter from a Lady de Grey, of Grobz, in which the shock was caused by a beetle, one of the common *elateridae*, and extended from the hand to the elbow on suddenly touching the insect; the other, caused by a large hairy lepidopterous caterpillar, picked up in South America by Capt. Blakeney, R. N., who felt on touching it a sensation extending up his arm similar to an electric shock of such force that he lost the use of his arm for a time, and his life was even considered in danger by his medical attendent.

MALLEABLE IRON.—M. Forquignon has published an extensive series of researches upon malleable iron and the re-heating of steel. Among other conclusions he attaches special importance to the following: 1. Malleable iron always contains amorphous graphite; 2. A casting may lose carbon and yet remain brittle if the original quantity of graphite is not increased; 3. A casting may become malleable without losing any sensible portion of its carbon; 4. If silicium is added to manganesian castings they are improved by reheating; 5. Hydrogen and nitrogen may unite with the carbon of a casting so as to make it malleable without the production of graphite; 6. The breaking load is always more than doubled, sometimes more than quadrupled, by annealing. It increases with the duration of the heating, very rapidly at first and then very slowly; 7. Ductility generally increases with the resistance to breaking, but after a certain limit it has a slight tendency to diminish.—*Ann. de Chim.*

Electric Lighting by Incandescence.

Experience has quite clearly shown that the only practical electric light for general use, must be derived by incandescence. The unsteadiness of such light from carbon points appears insurmountable. Hence, every effort in the way of finding or devising some more enduring material for incandescence, is hailed as another important step in the progress of electric lighting. The latest improvement in this direction is announced by J. Swan, in a paper read before the late meeting of the British Association at York.

The carbon shown by Mr. Swan was made from cotton thread treated with sulphuric acid, and then carbonized at a high temperature out of contact with the atmosphere. Paper is also prepared in the same way. By this mode of treatment the carbon, when last fall upon any hard substance, give out a metallic ring. The fiber, on close examination, seems welded together like the fibers of wrought iron. The carbons are very hard and at the same time most wonderfully elastic, an important point in securing durability. After being subjected for a while to the extreme heat of the electric current, the carbons appeared to develop increased hardness and durability for incandescence.

Sir Wm. Thompson, the distinguished English electrician, has experimented with these carbons with most satisfactory results. He reports a production of 390 candles per horse power. A lamp which gives, at a fair working power, a light of 50 candles, is capable of being pressed to 500 candles before the carbon is destroyed. Under such a pressure the light is described as fully equal in intensity to the arc light. So great and so susceptible is the incandescent power of these carbons, that, according to the paper read before the association, when a gas engine is employed to drive the dynamo-electric machine, the very remarkable result is arrived at that more light is thus obtained from a given quantity of gas exploded in the gas engine, than can be obtained from the burning of the gas in the usual way of producing gas light. The light, however, is very sensitive to irregularities of speed, so much so that even the overlap of the driving belt, causes the light to wink perceptibly at every passage of the joint over the pulley. With a proper speed regulation the light is more steady than the best gas light.

The paper concludes with the following paragraph: "Now that we can look to the method of electric lighting by incandescence as a perfectly practicable method, and now that we have the means of combining the economy of the mechanical generation of electricity with the constancy and many conveniences of voltaic accumulation, it is clear that the time is now ripe for the almost unlimited application of electric light to general purposes, and that engineers may, with much advantage, give their immediate attention to the many details which fall within *their* province in connection with the mechanical production and distribution of electricity on a large scale."

THE ABSORBING CAPACITY OF THE EARTH.—The generally accepted notion that the capacity of the earth for absorbing moisture is increased by a long continued drouth is entirely incorrect, the very opposite being the case. After a period of very dry weather, the surface of the earth becomes hardened, and to a certain degree impervious to water, and the first heavy showers that fall run off into rivulets and water courses, moistening the soil only to a very slight depth. The absorbing capacity of the earth is increased in proportion to the amount of moisture it receives, until it reaches a point of saturation, and then the water goes to feed springs and underground reservoirs. This can be easily exemplified in the case of pots containing common house plants. When the earth in these pots becomes very dry, and water is poured on the surface, it remains quite a while on the top without descending through the soil. But if, after the first application is soaked up, more water is applied, it sinks through the earth at once and disappears. After the earth is saturated with water, the latter flows through the hole in the bottom of the pot. So that great floods are always more liable to result from heavy rains succeeding very dry weather than from like rains coming after the ground has been soaked gradually by small showers.

CONSTITUTION OF COMETS.—M. Prazmowski concludes, from observations since 1858 by the spectroscope and polariscope, that comets are formed of a condensed portion, which constitutes the nucleus, surrounded by an incandescent gaseous atmosphere, which contains carbon and reflects the solar light, and of a swarm of disaggregated material which is not controlled by the cometary attraction but moves in obedience to universal attraction. In some comets the polarization of the light is strongly marked, while in others it is almost wholly absent. In the latter case he compares the structure to that of atmospheric clouds.—*Comptes Rendus.*

PURIFYING BISULPHIDE OF CARBON.—To purify bisulphide of carbon it has been proposed to agitate it with a concentrated solution of permanganate of potash till the violet tint produced becomes permanent, showing that the reducing action has ceased. The bisulphide is then washed with water, and, being so much heavier, is easily separated by a separating funnel. The result is a pleasant, ethereal-smelling liquid that must be kept from the action of light.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Horn Silver, Nov. 25th, $32,500; Barbee & Walker, 25th, $1,607; Horn Silver, 22d, $17,500; Richmond, 26th, $20.192; Horn Silver, 23d, $20,000; Wood River, 23d, $2,625; Hananer, 23d, $2,050; Standard Con., 26th, $82,381; Bodie Con., 26th, $5,272; Horn Silver 22d, $10,000; Tintic, 22d, $2,781; Barbee & Walker, 22d, $1,467; Northern Belle, 23d, $6,326; Wai Wera, 23d, $3,304; Christy, 26th, $2,361; Contention, 21st, $12,723; Bodie Tunnel, 25th, $2,571; Eureka, 16th to 21st, $16,515; North Belle Isle, 25th, $9,500; Head Center, 28th, $4,303; Star, 21st, $2,892; Northern Belle, 25th, $7,903; Bodie, 25th, $5,272; Silver King, 23d, $19,278; Independence, 30th, $6,000.

THERE have been 3,301 locations recorded in Wood River country since January 1, 1879. Doubtless 1,400 of this number was made this year. Of course, hundreds of claims have been staked off and left without recording.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday of last week, Vice-President J. P. Moore in the chair. Charles H. Bradford, John S. Doe and George Spaulding were elected life members.

The donations to the Museum were as follows: From Mrs. Hostetter, mortar and pestle from near San José, Cal. From W. J. Fisher, metate from Alaska. From J. G. Lemmon, cones of Pinus reflexa, Pinus Chihuahuna, Agave Schotti, Pinus edulis, Pinus Arizonica, wood and bark of Cupressus Arizonica.

From J. M. McDonald, insects found in Keystone mine 800 ft. vertically below the surface at Amador City, Amador county, Oct. 8, 1880, collected by Jas. F. Parks, foreman for the Keystone Con. Mining Co.

From R. W. Waterman, 18 specimens of dendrites, from specimens of heavy spar, sulphate of baryta—all from Mohave desert. From C. W. Brooks, specimen of flint.

Dr. H. Behr read a paper describing certain spiders found at a depth of 800 ft. below the surface in the Keystone mine in Amador county, Cal., describing their organization and probable ancestry. The paper we shall shortly print.

J. G. Lemmon read a paper on "Arizona Forest Trees," illustrating his remarks with specimens of branches, leaves, cones, bark, etc. This paper we shall publish in full shortly.

The two following self-explanatory letters were read:

Charles Crocker, President Southern Pacific R. R., San Francisco, Cal—DEAR SIR: In my absence from San Francisco on duty, I learn from the proceedings of the California Academy of Sciences, that you have given that institution, of which you have long been a member, the sum of $20,000, to aid in original scientific research.

As one of the workers in the cause for which the Academy was founded, for many years giving much of my unofficial time to its advancement, knowing the difficulties and the trials which it has encountered, and sharing the anxieties and the hopes and the earnestness of the the members, the council and the trustees, in its success, I ask that you will accept my sincere admiration and hearty thanks for this practical and munificent expression of your endorsement of the objects which prompt and sustain our labors.

I have ever contended for the beneficial and utilitarian ends which all pure scientific investigation must eventually serve, and I am certain, that on this coast especially, we shall see the people and the State benefited a thousandfold by such endowments. Believe me, very truly and sincerely,

Your Ob't Serv't,
GEORGE DAVIDSON,
Pres't Cal. Acad. Sci.

U. S. Coast and Geodetic Survey, Yolo Base Line, Nov. 10, 1881.

OFFICE OF THE SOUTHERN PACIFIC RAILROAD, COR. 4th & TOWNSEND STS. PRESIDENT'S DEPARTMENT.

Prof. Geo. Davidson, U. S. Coast & Geodetic Survey Station, Davisville, Cal. My Dear Sir: Your favor of the 10th inst., expressing your feelings on the occasion of my presentation of $20,000 to the Academy of Sciences, to aid in Original Scientific Research has been received, and I can assure you that it is very gratifying to me to receive letters of this character, from such distinguished men and workers as yourself.

I had long contemplated leaving a sum of money in my will for this purpose, but thought I was likely to live too long, and so concluded to do it while alive, fully impressed with the belief that it would be well and faithfully disbursed by your society. Yours very truly,

CHARLES CROCKER.

San Francisco, Nov. 12, 1881.

The Mining Share Market.

During the latter part of this week stocks looked up a little, particularly Union Con. A telegram from Virginia on the 20th, very encouraging, was as follows: The drift on the 2400 level of the Savage last evening reached the point where the incline will strike said level. If they cannot start the water out of the incline by firing a heavy blast at the bottom, they will tap it with the diamond drill. They are extracting 80 tons of ore per day.

A winze is being started on the 2500 level of the Sierra Nevada, at a point where low-grade ore was found while Senator Fair was in charge. The joint Sierra Nevada and Union Con. winze, in which the ore was found, is now nearly down to the 2800 level. It has cut through many streaks and seams of ore, all of which were dipping to the east.

At the north end work is progressing well in the Sierra Nevada and Union Consolidated. The 2700 station of the Union shaft and the joint winze will be connected in about 10 days. Once this connection is made there will be obtained a circulation of air which will permit of much prospecting being done.

At the joint Mexican and Union Consolidated winze the drill will soon be started from the 2700 station to guard against water, and if it shall be found safe to extend the drift now started, it will be pushed ahead. It will pass into some very interesting ground.

The *Free Press*, speaking of the mines at Bodie, says:

We believe that the Noondays will some day be great mines, so will Oro and Addenda and all that group of locations. The formation is such as to lead to such a conclusion. When the 1000-ft. level is reached in the Oro and the ground explored, there will be an ore body exposed that will astonish the country. The west cross cut on the 600 ft. level of the Red Cloud is approaching a good country, and things are liable to pop there some day, to use a street expression. The Bodie Tunnel people expect to get their mill in working order by the 1st, and then ore crushing will be resumed in good earnest. There is no change in the Syndicate, the ore production being about the same as previously reported in these columns.

In addition to the regular dividend the Standard pays this month an extra dividend of 75 cents.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MEDIAN.—Amador *Ledger*, Nov. 26: Work has been suspended for the present at both mine and mill. While the rock crushed paid more than expensee, still there is not sufficient ore in sight in the mine to justify entering upon another crushing. The shaft must be sunk deeper, and the mine opened up, and this the stockholders are not prepared to do right away, and hence the suspension of work until next spring. It is believed that the Median will turn out a permanent mine.

MORGAN TUNNEL.—On good authority wo are able to state that in the opinion of expert mining men, the ledge has undoubtedly been penetrated by the tunneling operations. It is badly broken up, it is true, but the hope is held out that the ore bodies will come together and form a well-defined ledge at a greater depth. The work of tunneling will be continued probably through the winter, but nothing will be done in the matter of putting up a mill until next spring.

MISCELLANEOUS.—A serious cave occurred in the shaft of Doyle's claim, in Hunt's gulch lately. Something like 100 tons of earth caved, putting an effectual embargo upon the further prosecution of prospecting operations. J. J. Stewart, of Butte, and Lowell, of San Francisco, are operating a quartz claim in a gulch about half a mile from Big Bar bridge. There is a shaft, 60 ft deep, on the property, which shows some quartz at the bottom. Work at present is confined to running a tunnel from the gulch to strike the ledge at a point 40 ft below the shaft. At the mine lately sold by Owen Kelly to Boston capitalists, everything looks lively. The indications under ground are sufficiently satisfactory to warrant the putting up of a mill. The 20-stamp mill at the Montirichard mine has been purchased, and is now being taken down for the purpose of being hauled to Hunt's gulch.

CALAVERAS.

CORRAL FLAT MINE.—Calaveras *Chronicle*, Nov. 26: Work is being vigorously pushed ahead in the Corral Flat mine. A very large quantity of gravel has been encountered in the drifts, which can be taken out very fast, faster in fact than it can be put through the mill. A clean-up, after a short run, was recently made, and though we are not informed as to the exact figures, we learned that it was highly satisfactory. A new pulley has lately been put in by which the mill can be run the requisite speed, and the pump and hoisting works kept in operation at the same time without running the pump beyond its regular speed. Everything is working well now, and the prospects for the mine to be remunerative are very favorable.

THE LAMPHEAR MINE.—The parties from Stockton who were here last week for the purpose of examining the Lamphear mine, have made a very flattering report in regard to the merits of the mine and considerable interest is being manifested in that piece of property. The parties report that the inducements for undertaking and working the mine were greater than what was represented. Especial pains were taken to learn the history of the mine, and the information obtained in every case was in its favor. We have known the mine for years, and we have always heard it spoken of by those who were best qualified to judge, that it is an excellent piece of mining property.

OLD JUDGE.—*Mountain Echo*, Nov. 22: The famous Old Judge mine, situated about one-half mile south of Douglas' flat, is again in working order. Some weeks ago a large body of earth settled into the main works, which, of course, necessitated considerable labor, in order to get everything in good working condition again. That task is now happily performed, and again the wheel of fortune moves.

EL DORADO.

JOSEPHINE.—Georgetown *Gazette*, Nov. 23: Supt. Hart, of the Josephine mine at Volcanoville, was down last Saturday, and left between $300 and $400 in this place, in payment for supplies, etc. We learn from Mr. Hart that their 10-stamp mill is kept constantly running, and that besides the force engaged in getting out ore and running the mill, they have three men at work making developments on other parts of the lode. The results so far are highly satisfactory. Their mine is on the east wall of the greenstone belt, and the ore resembles that of the Pacific mine at Placerville, which, we believe, lies against the west side of this same greenstone belt. The quartz mining outlook in this locality is really encouraging. Several mines about Georgetown have been bonded—some by bona fide capitalists and some by men for speculation in the event of a boom, which bids fair to visit this camp before next spring. During the past week no less than six mining capitalists have been up looking after mines in this vicinity. We understand that work of development is soon to begin on a number of our prospect mines, as well as on mines heretofore worked with varied success by men who did not possess the capital and energy to work their claims as they should be to make them profitable. Another large mining enterprise has just started up at Volcanoville, under the management of Geo. Bower, well known in the mining circles of this divide, and Archie Borland, one of the solid men of San Francisco. They have purchased the old Graves quartz claim, famed for its rich ore, and have christened it the Garfield mine. A force of men have already been put at work, and a tunnel will be driven in to tap the lode 100 ft below the surface. The public may rest assured that these men mean business. The North Cedarburg, Greenwood district, will be started up right away with full force, by W. N. Martin & Son. This noted mine bears a good record, few mines in the county surpassing it in its large yields. It was from this mine that the renowned $6,400 piece of quartz (about 18 inches square) was extracted some years ago. Martin & Son are now about to hydraulic and uncover the original ledge, which it is confidently believed will even surpass that part of the lode already worked in richness. We wish them success.

INYO.

MINING TROUBLE.—Inyo *Independent*, Nov. 29: On Tuesday last, at Darwin, an armed force of some 10 or 15 men proceeded to the Defiance mine and took possession, ousting the men working for Martin Mee, who claims the mine by relocation. There was no resistance offered. It is understood that the party acted for Reddy & Gormau, who recently purchased the title of Taber & Harker to the Defiance furnace and mine.

MARIPOSA.

DILTZ MINE.—Mariposa *Gazette*, Nov. 26: Capt. Diltz, owner of the Diltz mine, called upon us on Thanksgiving Day. All he gave us was a bit of information, that he had commenced operations upon the west end of his mine about 1,500 ft from the shaft and stope heretofore mentioned. The vein of auriferous ore continues the whole length of the claim, and enough has already been seen to convince anyone of its vast richness. The work in the stope and shaft still continues with good results.

THE NEW SILVER MINE.—In the issue of the *Gazette*, of Nov. 12th, in speaking of this mine, which is located near the Modesto silver mine, and owned by Mr. Moses May, of Modesto, an error crept in which we very much regret. We stated in the paragraph that "only one test had been made, which assayed $27 per ton," which should have read $2,700 per ton—some difference.

NEVADA.

CLAIM LEASED.—Nevada *Herald*, Nov. 26: James E. Frederick has leased his gravel claim at Columbia hill for six years, to the Meen Lee Hong Co. The lessees propose to work the mine by hydraulic process, and in order to do so, will run a bedrock tunnel, through which to wash their tailings. When the mine is fully opened they will employ

about 40 men. The Broderick claim is regarded as valuable mining property and the company who have leased it will probably receive good returns. A rich streak of blue gravel extends through the claim, and the gold obtained is very coarse. We are not informed as to the terms upon which the lease was made. We wish Mr. Broderick success in his future undertakings.

MURCHIE.—Nevada *Transcript:* The Murchie mine is looking well, and their 10 stamp mill is kept running night and day. Contracts to sink the shaft are to be let every month hereafter. If this mine was opened as many others are, in this vicinity, the company would be able to pay dividends. The Providence M. Co. are still making new improvements to their property. It is one of the best quartz mines in California and continues to pay its owners handsome dividends. It will take many years to take out the quartz that is in sight. Several New York capitalists are expected here in a few days to examine some of the idle mines in this vicinity which are known to be good, but cannot be opened without coin. The Cold Spring Co. are getting along very well with their tunnel. They have about 300 ft more to run to reach the pay channel. The Nevada City mine continues to look well, and the owners are perfectly satisfied with their property. The Hershman mine will be ready for work in about a week. They have nearly completed the necessary labor for starting up. The Wyoming mill is running night and day, and the rock that is being taken out is looking very fine. The stoppage of the hydraulic mines cuts off about a million per month in this county alone. If all the hydraulic mines in this county were being worked times would be lively. There are more quartz claims being worked in this township now than ever before in its history.

MONO.

STANDARD CON.—Bodie *Free Press*, Nov. 29: The shaft was sunk during the week 10 ft; total depth 1,110 ft. The character of the rock remains the same. The total length of the south drift on the 500 level is 450 ft showing the vein in the face to be 4½ ft wide. The different stopes show no particular change. All are looking well and yielding the usual quantity of ore. On the 385 level the ledge is 10 ft wide in the south and about 30 ft wide in the north end of the mine. On the 550 level the vein is 15 ft wide of clean ore. During the week there were extracted and shipped to the mills 1,274 tons of ore from the 300, 385, 500 and 550 levels. The average pulp assay for the week was $31.73. The amount of bullion shipped to San Francisco was $82,381.60.

BODIE CON.—There were 90.0 tons of ore hauled to the mill durlug the past week. On the 23d inst. connection was made between the south drift from winze No. 9 and the north drift from winze No. 6. The bullion shipment was $5,272 38.

NORTH NOONDAY.—An upraise has been started from the 512 to the 412 level. The No. 2 vein is larger and giving good assays. Ore for the mill is being stoped from the 212, 312 and 412 levels.

TIOGA.—The north lateral drift east of the shaft, 982 level, is now in 403 ft. On the 520 level some necessary work is being done in repairing the Syndicate tunnel.

BODIE TUNNEL.—The only work being done in the mine at present is repairing on Ledge No. 20 nnd enlarging the station nt the intersection of ledges Nos. 20 and 21. The tunnel has also beeo undergoing repairs. The chutes are being filled up with ore in enticipation of the mill being completed hy the 1st, and ready for crushing on the 5th. The supply of water for the new mill will come from the Bulwer-Standard mill, nnd a large force of men are now engaged in making a ditch for the pipe.

NOONDAY.—Ore is being stoped from the 212, 312, 412 and 512 levels and the mill kept steadily nt work.

PLUMAS.

A WONDERFUL MOUNTAIN.—Orcenville *Bulletin*, Nov. 23: The mountain just south of Greenville is certainly a wonder. Rising to a hlghth of about 2,000 ft above the valley, it is covered with a rich growth of giant pines to its summit. On nearly the whole of its circumference it has been pierced by tunnels, but these tunnels have not yet gone much below the surface. As the tuanels are driven deeper, the ledges get widor and the ore richer. The Oakle Canyon mine, the Green Mountain, Crescent, Taylor, Plumas, Indian Valley, Union, New York, Cherokee and Southern Eureka mines; all of theso ere in this mountain. Many other unnamed ledges, as good as any now being worked, are located, but not worked, the owners being too poor to put up the requlred mechinery. Meny of the ledges are from 5 to 30 ft in width, and of uniform richoess for hundreds of feet nlong the ledge. When the necessary capitnl, energy end skill nre united for its thorough development, this mountain will yield millions of dollars to the wealth of the country.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—*Enterprise*, Nov. 27: On the 2700 level the joint Union Consolidated winze has been extended 47 ft nnd the west drift 19 ft.

OPHIR.—There has been 281 tons and 1,200 lbs of ore extracted from the croppiugs, nnd 474 sent to the mill.

UNION CONSOLIDATED.—At the joint Mexican winze have completed the 2700 statioh and put in guides and cages

UNION SHAFT.—Are repairing the drift to the Sutro tunnel on the 1600 level, and cutting out a hoh pit on the 2900 station.

UTAH.—Cutting out a stntion for a hoh pit at the 2250 level. The drill hole on the 2500 level has been advanced 105 ft.

CON. VIRGINIA.—Still doing work for ventllation purposes in drifts and winzes connecting with the old Con. shaft.

CALIFORNIA.—Still doing ventilation work on drifts and winzes connecting with the old Con. Virginia shaft.

MEXICAN.—At the joint Union Con. east winze have completed the 2700 station and put in guides and cage. On the 2700 level the joint Union Con. enst drill hole has been extended 60 ft.

ALTA.—The drain drift on the 1250 level is also progressing well. The water is gradually increasing.

YELLOW JACKET.—The drill hole east from the face of the east drift at the face of the north lateral drift, on the 2824 level, is this day in 172 ft, and is still being advanced drilling shows quartz and porphyry, giving low assays. On the 3000 level the east cross drift has been run 33 ft, making the present length of the same 221 ft from the switch; ground hard, with litt'e water.

CALEDONIA.—Pumps have been run an average of 83 hours per day and consumed 4 cords of wood per day. Forman shalt has been sunk nnd timbered 15 ft; total depth 2,245 ft.

ALPHA.—Are repairing the old air pipe taken out of Imperial shaft and putting it down the incline to the 2000 level.

CON. IMPERIAL.—Have finished putting in the new pipe in the shaft and are now putting in the repaired old pipe in the incline down to the 2000 level.

HALE AND NORCROSS.—Since the final opening of the incline hulkhead, on the 14th inst., the west drifts on the 2000, 2100 and 2400 levels have been secured and closed up, thereby confining the heat to the 2200 level workings.

OVERMAN.—Have cut a station in the 2275 level for air receivers and moved them down from the 1600 level The drill hole on the 2275 level was run in the course of the drift 185 ft, when the rod broke and we had to abandon the hole.

SOUTH TONNEY.—Report for the week ending Nov. 22: The distance of the face from the Yellow Jacket turning point is now 1,865.23 ft, and to a point 200 ft west of the Forman shaft, 1,568.08. South lateral, repairs—The repair shift put up 4 sets of new timbers and removed 2 old sets, besides lagging up and making the usual repairs. They have also been employed a portion of the week in cutting out for the new cooling station and moving the switch.

BRISTOL DISTRICT.

TEMPEST AND MAYFLOWER.—Pioche *Record*, Nov. 19: The two Bristol bonanzas, the Tempest, the property of Messrs. Gilmer, Salisbury & Co., and the Mayflower of the Bristol Silver Mining Co., are pronounced by experts to be two of the biggest mines in the State to-day. Both have huge bodies of high grade ore in sight, of unknown extent, and those who have worked in the Raymond & Ely say that the Mayflower and Tempest are away ahead of that mine at its best days. By next spring, when the Tempest and Iron mine reduction works are erected, and the Bristol mill in trim, Bristol will show an output, with the Day silver mining company, of over $300,000 per month; a showing that will place Bristol to the front as one of the leading mining camps of the coast. The Bristol mill is still pounding away on $200 rock, chipping this week by Wells, Fargo & Co.'s express five bars of bullion, 984 fine, valued at $11,210; making a grand total of over $26,000 for the 13 days that the mill has been running. This is certainly a splendid showing, but as the ore is very moist and the facilities for drying are somewhat limited, the battery is consequently not worked up to its full capacity, but arrangements are now being made for doing away with these drawbacks, and an additional 10 stamps added, which will then enable the company to turn out $75,000 a month. The Bristol furnace of the Day company, after a long and successful run, was closed down last Friday. The ore that is coming down is of a high grade and easily worked, and by the time the furnace starts up again, which will be in about 2 weeks, there will be several hundred tons of this character of rock on the dump, which, with the heavy lead ore that is being shipped from the Mendha, this next run will surely be as profitable a one for the company as the last.

BULLION MINE.—The Day Co. has placed a few men at work prospecting in the mine. The old miners, who worked in the mine when it was yielding large quantities of good ore, say that the formation of the ground denotes a large body of ore somewhere in the immediate vicinity.

CANDELARIA DISTRICT.

LUCKY HILL.—*True Fissure*, Nov. 20: Under the energetic superintendence of Mr. Mechling this mine has had new life put into it. At a depth of 260 ft on the incline 2 crosscuts have been started—1 to the southwest and the other to the northeast. These crosscuts are from the east drift and have attained a distance of 26 and 37 ft respectively. The formation in the southwest crosscut has been a little refractory and progress has been necessarily slow, but in the northeast crosscut the ground has broken well. Some disadvantage has been encountered in handling the waste while waiting the putting in of a turntable and laying track.

MOUNT DIABLO.—Connection has been made between the intermediate and the north crosscut from the bottom of winze No. 1. At this point there is a bunch of ore about 2 ft wide on which an upraise hes beeu started. The ore essays from $60 to $80 per ton. In the east drift, from this crosscut, there is a 10-inch streak of $70 ore that looks extremely promising for opening. A drift is being run easterly from the north crosscut at the bottom of winze No. 3, on the third level, which is in 15 ft. The east drift on this level has been following a seam of $85 ore during the past few days that looks very well.

NORTHERN BELLE.—The fourth shaft level has shown no very material chenge during the week The west drift has been extended 12 ft in favorable looking ledge matter giving low nssays. The upraise is also in a promising formation. There are being extracted and sent to the mills about 60 tons of ore deily. Both mills are running as usual and doing the regular amount of work. Bullion shipments for the week endmg Nov. 23d amounted to $20,037 69. Shipmeats on November account to Nov. 23d, $90,896 95.

CHERRY CREEK DISTRICT.

THE TEACUP SWINDLE.—White Pine *News*, Nov 26: Last Monday being the day on which the Teacup Co.'s notes fell due, there wesn leverish excitement among the holders of notes here to learn if they would be paid as per agreement. Supt. Smith was consulted, but that hitherto ever-hopeful represen'ative of the company could give no assurnnce. He knew nothing about the matter. Later in the day a telegram was received from Wells, Fargo & Co.'s banking house in New York, stating that the notes had gone to protest. Then a rush was made for Justice Lander's office, and attachments were issued on every detnched piece of property at the mill or mine. Suits were also commenced in the District Court nt Hamilton against the property of the company. It is now apparent to our people that, from first to last, this New York corporation was nothing but a swindling concern.

ESMERALDA DISTRICT.

HUMBOLDT MILL AND MINING COMPANY.—Esmerelda *Herald*, Nov. 26: At the mill the meu are still at work prepering for the machinery. At the mine developments are being made to prepare to take out ore when the mill is ready to crush.

THE CENTENNIAL MINE.—Messrs. Oroth & Ball are still at work at the bottom of the incline and pushing downword. The ledge shows no signs of "petering." By spring the owners will have developed a million or more.

THE CORTEZ MINE.—The lower tunnel has reached the ledge, and now the miners are engaged in making the connection with the incline shaft on that level, the tunnel having struck the ledge some distance from the incline shaft. Everything moving along nicely.

EUREKA DISTRICT.

EUREKA CON.—*Sentinel*, Nov. 26: Supt. Reed writes to his company nt San Francisco as follows: Nothing new to report in relation to the mine this week. The 240 squares of tin roofing arrived for the Locan shaft, and is now being put on the building. The furnace is working and reducing the usual quantity of bullion.

ARIZONA.

DOSORIS CAMP.—Arizona *Democrat*, Nov. 25: Supervisor Cline came in yesterday from the Dosoris camp. We learn that prospectors are busy at work in that neighborhood, and with good results. Work on the Dosoris is pushed steadily along. They are down at least 50 ft in the main prospecting shaft. Joseph Taylor is foreman, and has three shifts of men at work in this shalt and two shifts stoping ore. There is also n force of men prospecting on the Buzzard. There are three shafts on this claim, and a fine showing of rich ore. The Raven is standing idle at present. The ore is chiefly chloride and argentiferous galena. There is a business air pervading the camp. This camp will soon be producing bullion. Townsend Cox and his syndicate are now heavy New York capitalists, and we are glad to note that their plant in our county bids fair to be a bonanza.

HACKBERRY ITEMS.—This village is assuming metropolitan airs on account of the near approach of the railroad. The people are waking up from their long sleep of the past few years, all caused by the closing up of the quartz mill at this place. There are several well paying mines in this vicinity, but they are unable to work them on account of the great cost in getting machinery and tools The opening of the railroad to this place will be the signal for a better time. A Boston company has got control of the quartz mill here, which they are overhauling and repairing, and will start up as soon as they can get machinery enough to run it. This place is sure of one railroad, and the prospects are that it will have two.

BIG BUG.—Cor. Arizona *Miner*, Nov. 25: During the past week we paid a visit to the Sterling, a mine owned by Messrs. Stevens and Betts. They have a shaft down about 58 or 60 ft, with a pay streak of 24 inches in the bottom, an average of 20 inches for the last 10 ft, and an average of 16 inches for the entire length of shaft. Their ore assays from $52 to $374 in silver and some gold, with an average assay of $142. We were also shown the Nonesuch, a mine owned by Mr. Stevens. He has a tunnel started in along the vein, and a fine, large body of ore on the dump.

NOTES.—Arizona *Sentinel*, Nov. 24: O. F. Townsend has just completed the survey of the Bull Dog mine, East Silver District. Work is about being started on this promising ledge. The Iron Cap Co. early in January will renew operations upon their mine, in a lively way. It is the intention of the company to thoroughly develop the Iron Cap, which is already one of the deepest mines in the district, and few if any can make a better showing. Mr. Thos. Ollchrist has purchesed all of Mr. Iager's interest in the "Daniel Broone," "Offspring," "Outside" and "Remnant." Tom has unbounded confidence in the camp; also bought out Sam Dyer in the "Remnant." The output of ore on the Black Rock continues as large as ever, and seems to increase in richness. This property is being developed in a systematic and business-like manner, and will undoubtedly prove a heavy bullion producer at an early day. A rich strike has been made in the Silver Glance mine. A large body of sand carbonates has been opened up, in the tunnel, besides a streak 18 inches wide of high grade sulphuret ore. Mr. A H. Cargill is to be congratulated upon his bonanza.

NOTES FROM DOS CABEZAS.—Arizona *Journal*, Nov. 22: From Mr. A. E. Fay it is learned that the Cincinnati and Pittsburgh company, at Dos Cabezas, have their new 20-stamp mill nearly ready for operations. While they own several promising mines in that district, they propose to do custom work, and thus offer inducements for poor miners to develop their own properties from the proceeds of the ore milled. Mr. W. W. Tice is the superintendent of this company. Mr. W. A. Nevills, superintendent of the Commonwealth Co.'s mines, is pushing work as rapidly as possible, with the very best prospects of rich returns. The Bear Cave mine, upon which he is concentrating a large force, shows a large body of rich ore, and it is thought will prove equal to any in Cochise county. The outlook for Dos Cabezas is exceedingly bright.

STRIKE IN SILVER BELT.—On Saturday night the workmen in the Silver Belt struck a vein of red ore, similar in appearance to that of Grand Central. The vein dips quite flat to the west, as the ledge does further south. While the ore thus far taken out has no great value, the strike itself is of the greatest possible interest to the district proving conclusively that the great Contention lode continues directly on to the northward towards the mesa. The strike is in a drift running west from the shaft and about 150 ft therefrom, bringing the lay of the vein at this point on the direct line of the ledge, as traced from Grand Central through Contention, Head Center and Tranquility. A few weeks will be required to determine how extensive the ore is likely to prove this far north on the lode.

TYNDALL DISTRICT.—Arizona *Journal*, Nov. 20: There is great activity at present all through the Santa Rita mountains in mining matters. This is especially true of Tyndall district. Mr. A. B Casey has commenced the preliminary foundation for a water jacket furnace, which will be put up without delay. Several important sales affecting property in this district are now being negotiated. Mr. James Campbell will commence work on the group of mines in which he was formerly largely interested, in behalf of the Eastern capitalists who have recently come into possession of the property. This syndicate represents ample capital, and as the property has always ranked very high as a prospect, we anticipate some very satisfactory results as the work progresses. The road from here to the district will be much improved by the new overseer, Mr. Mark Lully, who will commence work on it without delay.

A NEW ENTERPRISE.—Arizona *Journal*, Nov. 27: A company has just been formed in New York, called the O. K. Con. M. Co. They own 3 promising claims near Old Mowry, in Patagonia district, and will commence active work at once. The near approach of the Atchison, Topeka and Santa Fe road will render all these large bodies of low-grade ore in that vicinity very veluable. The new company starts out with the finest prospects. Mr. Covington Johnson, superintendent of the Hermose, is also superintendent of the new company.

RANDOLPH DISTRICT.—Pinal *Drill*, Nov. 19: Randolph District is 14 miles northwest of Pinel. Here ere several rich strikes nnd new locations. The Diamond Peak has large quartz croppings, which contain oxides and galena ores, beering silver. There are a large number of small veins, all centering in the main vein, very rich in appearance, with indications of gold. This mine is located hy Julius Baeuerlein, B. W. Kellogg and Thomns Oravce. The Snowflake, about 1½ miles easterly from the Diamond Peak, is in granite formation, carrying galena, chlorides and horn silver. The vein shows 3 ft wide on the top. The Germania, 2 miles southwest from the Snowflake; discovered and located by same. This is on another ledge with large croppings. The above mentioned parties also discovered a large gold ledge, which they traced for some distence, and washed out gold therefrom in a horn spoon, but had to leave on account of stormy weather.

COLORADO.

THE PELICAN AND DIVES.—Georgetown *Courier*, Nov. 24: Work at sinking the Pelicen-Dives mein shaft has now been suspended for about 3 weeks, on eccount of the flow of water being so strong that e pump will be necessary to keep the shaft clear while sinking is progressing. The shaft is 350 ft deep. Nothing new of importance has yet been developed in the lower workings. There are over 60 men employed in the mine, from 40 to 50 of them being lessees. The lease of Coughlin, Fitzpatrick & Co., in the stope over the 2½ tunnel level on the Unicorn, is in excellent pay, also the lease of Lampshire & Co., on the Eagle Bird. The other lessees are doing moderately well.

THE STEVENS MINE.—Work is steadily progressing at sinking the main shaft of the Stevens mine, which has now reached a depth of 160 ft below the tunnel level and 25 ft below the 11th level. The ore vein averages in the shaft and 11th level stope about 8 inches in thickness.

THE KING LODE.—A house is being built at the mouth of the adit on the King lode, situated on Bard creek and owned by Mrs. Ford, and as soon as it is completed work will commence at developing the lode.
